ABSTRACT

The results of a study on the fauna of land molluscs from Isola delle Femmine Nature Reserve (NW Sicily, Italy) (Gastropoda Architaenioglossa Pulmonata) are here described. In this small island 23 species have been found, 6 of which are Sicilian endemic taxa. *Siciliaria leucophryna microinsularis* n. ssp. endemic to the Isola delle Femmine (or Isola di Fuori) is described. For each species ecological, distributional data and information on their presence on this island are provided.

KEY WORDS

Conservation biology; micro-insularity; faunistic; land molluscs; Sicily.

Received 06.04.2020; accepted 03.06.2021; published online 04.08.2021

INTRODUCTION

The western Mediterranean Sea contains more than 1000 small islands, often less than 10 Km² wide. Some of them are poorly known or still to be explored. A lot of these host local endemics and have a more or less high biodiversity rate. In addition, they constitute a refuge area for many regional endemisms or threatened species of the neighbor areas like big islands or continental coast (see, for example, Lo Cascio & Pasta, 2012; Muscarella & Baragona, 2017; Lo Cascio & Sciberras, 2020).

Small islands or archipelagos should play a significant role in conservation programs, and more investigations and deeper taxonomic knowledges

are needed for this purpose (Minelli, 2012; Vela & Pavon, 2012).

The aim of this work is to increase the knowledge on the living land molluscs of the Isola delle Femmine (or Isola di Fuori), a small island, on the north-western coast of Sicily (Italy).

Isola delle Femmine Nature Reserve was established under decree n° 584, 01/09/1997 (Suppl. Ord. G.U.R.S. n° 3 the 16/01/1998) by Sicilian regional Government (Catalano et al., 1979) and managed by LIPU/Birdlife Italia.

This island is a part of the regional protected areas belonging to Nature 2000 network under European Direttives 79/409/CEE (Birds Directive) and 92/43/CEE (“Habitat” Dir.) as Site of Community Importance with code ITA020005

(Isola delle Femmine). Afterwards, on the island was established a Geosite with decree D. Ass.R. Sicilia n° 106 del 15 aprile 2015. Lastly, Isola delle Femmine was declared to be a Special Area of Conservation under European Direttive 92/43/CEE (Riggio & Massa, 1974; Riggio & Raimondo, 1992; Di Dio, 2011).

The reserve belongs the Municipality of Isola delle Femmine that adjoins Palermo (Sferracavallo) to the East and Capaci to the west. Due to its proximity to the coast the island has been the theater of many human activities, which ultimately resulted in a considerable environmental stress. Since Roman age a fish factory with an adjoining “tonnara” was operating on the island. On the highest point of the island (36 m above sea level) there is a XVI sec. sighting tower, called “Torre di Fuori” (Figs. 7, 8) opposed to the “Torre di Terra” building on the mainland (La Rocca, 2004). The tower, as we can see it, was commissioned by viceroy Marco Antonio Colonna to the military Tuscan architects and engineers Tiburzio Spannocchi and Camillo Camilliani (Mazzarella & Zanca, 1985; Maurici & Lucido, 2008).

Until 1997, year of establishment of the reserve, herding was practiced. During autumn sheep and goats were transported by boats, while cows and horses came swimming and left to graze on the island until spring. Other human-caused environmental disturbances were the practice of cutting trees to obtain lumber, the harvesting of dwarf palm leaves (*Chamaerops humilis* L.) for the artisanal manufacture of brooms, fires started to stimulate grass renewal and harvest of edible land snails.

The wild rabbit, *Oryctolagus cuniculus* (Linnaeus, 1758), was introduced to the island for hunting purposes. Later the colonization by Norway rat, *Rattus norvegicus* (Berkenhout, 1769) took place. Currently, on the island there is a Yellow-legged Gull *Larus michahellis* (Naumann, 1840) nesting colony.

As part of numerous research projects on flora and fauna of the islet undertaken by the managing body of the reserve, a study on land snails and slugs has been carried out since 2002. The work, intensified over the last year, has allowed us to achieve a good knowledge on the diversity and consistency of these populations, subject of this work.

MATERIAL AND METHODS

Study area

Geographical and geological setting. Isola delle Femmine ($38^{\circ} 12'36''$ N $13^{\circ} 14'10''$ E) is located to the northwest of Sicily, near Palermo, along a stretch of coast between Capo Gallo and Punta Raisi, in the Gulf of Carini. A 2 meter deep and 400 meter long arm of sea separates the island from the mainland (Figs. 1–6).

The islet covers an area of about 14 hectares and has an almost oval shape. Its major axis, NW-SE oriented, is 575 m long, its maximum width 325 m, and the highest point reaches 36.80 m asl where an ancient tower was built.

Three slopes start from the peak of the island and face south-east, south-west and north, respectively. The former extends for 300 meters and gently descends from an altitude of 35 meters, down to the sea level, with an almost flat course in the last stretch. This side is the least exposed to the action of both winds and washout. The south-west side is narrower and characterized by a steeper slope and greater outcrops of rock. Finally, the north side, very steep and rugged, consist mainly of sheer rocks and appears to the most exposed to the action of the winds and sea erosion. There are no freshwater springs on the island.

The study area is part of the Apennine-Maghrebian chain (Grasso, 2001) and consist of a deformed rocky substrate of the Mesozoic-Tertiary age and a Plio-Pleistocene coverage of clastic deposits. Such a rocky substrate is the extension into the sea of the panormid soils emerging in the hinterland and consists of limestone and dolomitic limestone of the Upper Jurassic-Lower Cretaceous age (Catalano et al., 2013a, b).

The study area belongs to the Palermo Mountains, a sector of the emerged Sicilian FTB (Sicilian Fold and Thrust Belt) that is a segment of the Apennine-Tyrrhenian System and whose building up refers to both the post-collisional convergence between Africa and the complex “European” crust (Bonardi et al., 2003) and the coeval roll-back of the subduction hinge of the Adriatic Ionian-African lithosphere (Doglioni et al., 1999; Catalano et al., 2013a, b). The tectonic edifice is therefore the result of the piling up of deep-water units and carbonate platforms

(Imerese and Panormide: Catalano et al., 2013b). Such tectonic units settled after the lower Miocene (Abate et al., 1978) while the carbonate rocks, described above, are the basements of the Plio-Pleistocene deposits visible in the coastal strip.

About 19,000 years ago, maximum of the regressive phase of the Wurmian glaciations brought the sea level 120 m below the current value (Segre, 1969; Ulzega et al., 1980). Subsequently, approximately 5,000 years ago, the positive change in sea level happening during the so-called Versilian "transgression" caused the sea level to rise to current altitudes with a maximum of about 2 m (Segre, 1969; Ulzega & Ozer, 1982).

Climatic considerations. The average annual rainfall in the area amounts to 632 mm and it is mainly concentrated in the autumn-winter seasons, while the average annual temperature is 19.6 °C as recorded by a thermo pluviometric station located in the village of Isola delle Femmine (4 m above sea level) (Duro et al., 1996). The bioclimatic indices derived from the thermo-pluviometric data show a Mediterranean-type macrobioclimate with an oceanic rain-seasonal bioclimate (Rivas-Martínez, 2008). The same indexes, in particular, determined an upper thermo-Mediterranean thermotype and lower dry ombrotype, respectively.

The flora of the island. According to the last census (Caldarella et al., 2010), the vegetation of Isola delle Femmine includes 219 infraspecific taxa. Of these, 105 were confirmed with respect to the previous census (Di Martino & Di Trapani, 1964). Present life-form spectrum puts in evidence the prevalence of therophytes (ca. 62%), followed by hemicryptophytes (ca. 20%), geophytes (ca. 9%), chamaephytes (5.5%), nanophanerophytes (2.3%) and phanerophytes (1.8%). As concerns chorological spectra, the Mediterranean element still is the most common (ca. 33%), while endemic and subendemic elements are very poorly represented (6 taxa, i.e. 2.7% of the local vascular flora).

The primary landscape in the central sector of the island consists of Mediterranean maquis that moving towards the coastline progressively turn in belts of halophilic and halonitrophil vegetation (Figs. 9, 10). The dynamism of the vegetation is slowed down by the extreme environmental conditions, partly

exacerbated by the poor soil evolution and by the high levels of sodium chloride in the upmost portion of the soil and originating from marine aerosol deposition (Caldarella et al., 2010).

Currently the flora of the island appears to be dominated by *Malva* spp., *Pistacia lentiscus* L., and *Pennisetum setaceum* (Forssk.) Chiov.

The fauna of the island. After the eradication of the European rabbit *Oryctolagus cuniculus* and of the Norway Rat *Rattus norvegicus* (Canale et al., 2019), the vertebrate fauna mainly reduced to few species of nesting birds including a colony (about 500 pairs) of the Yellow-legged Gull *Larus michahellis* Naumann, 1840 (Massa et al., 2021); the Sardinian warbler, *Sylvia melanocephala* (J.F. Gmelin, 1789); the Blackbird *Turdus merula* Linnaeus, 1758, the Zitting Cisticola *Cisticola juncidis* (Rafinesque, 1810), the latter nesting discontinuously only (LIPU, 2009, 2011).

Furthermore it is worth to mention the occasional nesting (in the 2003 and 2004) of the Jackdaw *Corvus monedula* (Linnaeus, 1758) (LIPU, 2003, 2004) and an attempt of nesting in the last few years by the Raven *Corvus corax* (Linnaeus, 1758).

The reptiles are present on the island with five species: *Hierophis viridiflavus carbonarius* (Lacépède, 1789), *Chalcides ocellatus* (Forsskål, 1775), *Podarcis siculus* Rafinesque, 1810, *Tarentola mauritanica* (Linnaeus, 1758), and *Hemidactylus turcicus* (Linnaeus, 1758) (LIPU, 1999, 2004).

Very little is known about invertebrate fauna (Carapezza, 2006) also because in the entomological collections of the past it is not clear whether the labeling "Isola delle Femmine" refers to the islet or the stretch of coast where the homonymous town stands (Aliquò, 1996).

Our ongoing studies are focused on invertebrate fauna as it turns out to be significantly rich and diversified.

Methods

Ecological observations on land molluscs were performed directly in the nature reserve and allowed discovering of living specimens and shells suitable for the subsequent morphological and taxonomic classifications. Two sampling methods were employed, namely visual recovery and

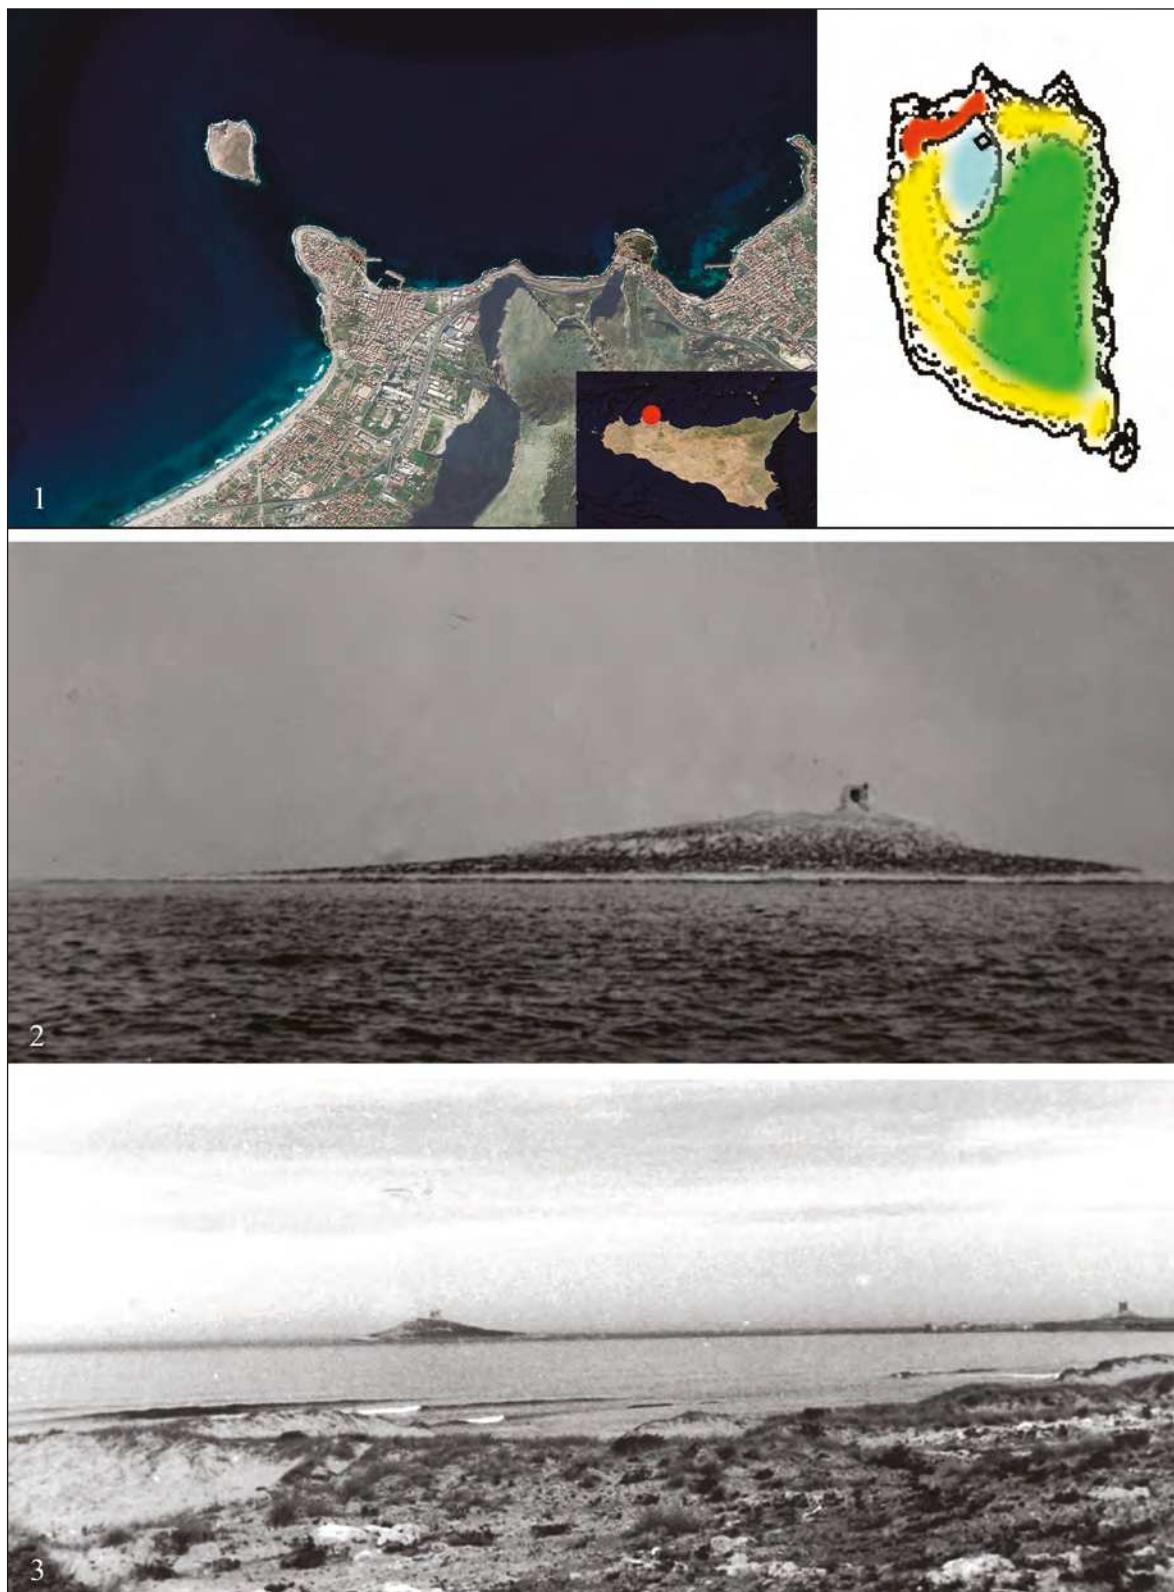

Figure 1. Isola delle Femmine Nature Reserve (NW-Sicily, Italy); on the right, in yellow: open areas with rocks and vegetation, green: *Pistacia lentiscus* maquis, red: rocky walls, light blue: ruderal area. Figure 7. Isola delle Femmine, southern slope and the Torre di Fuori in the highest part of the territory.

Figure 8. Isola delle Femmine, Torre di Fuori.

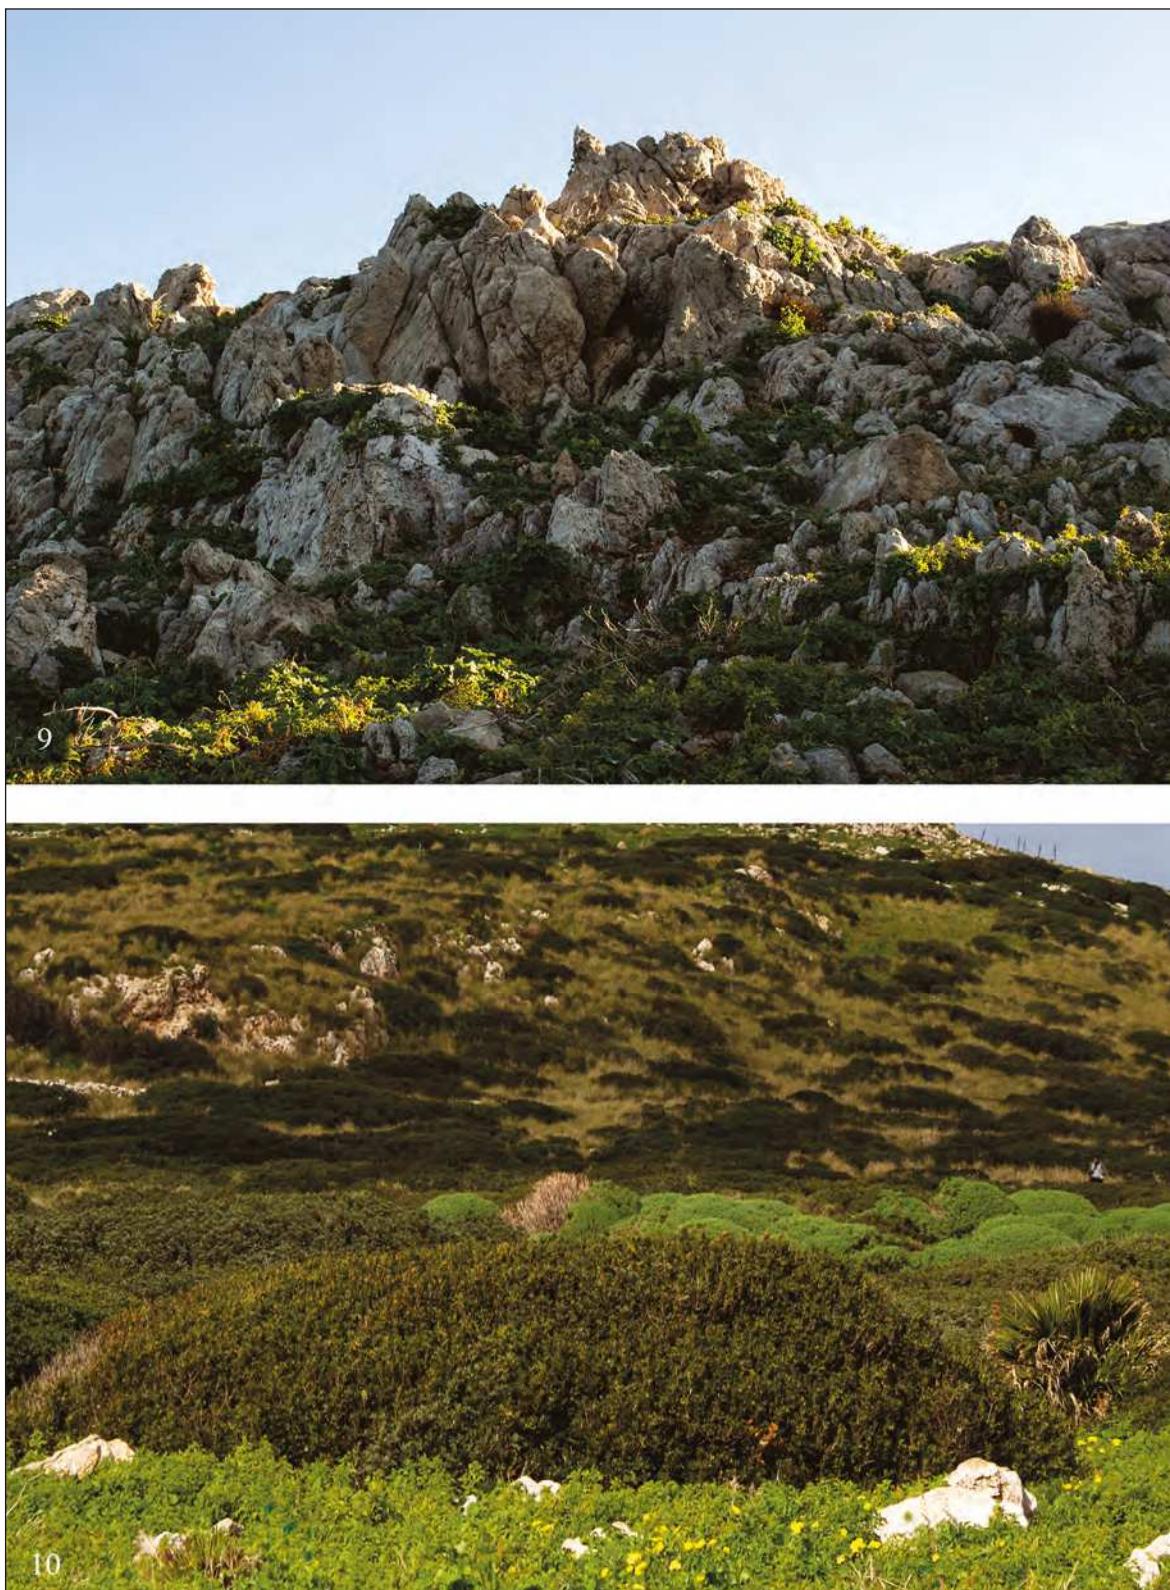

Figure 9. Isola delle Femmine, limestone rocks on the northern slope. Figure 10. Isola delle Femmine: *Pistacia lentiscus*, *Euphorbia dendroides* and *Chamaerops humilis* on the southern slope.

sieving of debris. For the visual collection, a careful search was carried out throughout the island and in all possible microhabitats. Animals and shells were then collected from limestone rocks, the walls of the Torre di Fuori, the ground, under large and small stones naturally lying on the ground, and under organic remains such as decaying either organic plants or natural animals, near seagull nests, mastic litter. The aim of the research was to find species with different ecological requirements. The species were classified in laboratory through the morphological analysis of the shell and genitalia with the aid of an Optika stereomicroscope. Height and maximum diameter of the shell along with some parts of genitalia were measured (in millimeters) by a digital gauge. The photos were taken with a Canon EOS 100D camera. Some specimens were fixed in 80% ethanol and the reproductive system was extracted using a scalpel, scissors and needles. Taxonomic references are mainly based on MolluscaBase (2021) and other cited bibliographical references. Chorological categories are based on La Greca (1962) subsequently elaborated by Vigna Taglianti et al. (1993, 1999) and Parenzan (1994).

Biological and ecological data are reported for all species. The materials used for this study were preserved in the following Museums and private collections: F. Liberto, Cefalù, Italy (CL); Museo Civico di Storia Naturale di Genova "G. Doria", Italy (MSNG); Museo Civico di Zoologia, Rome, Italy (MCZR); Muséum d'Histoire Naturelle de Genève, Switzerland (MHNG); Natural History Museum University of Florence Zoological Section "La Specola", Florence, Italy (MZUF); A. Reitano, Catania, Italy (CR); I. Sparacio, Palermo, Italy (CS), R. Viviano, Palermo, Italy (CV).

ABBREVIATIONS AND ACRONYMS. spiral lamella; SP: sutural plica; UOS: uterine ovispermiduct; V: vagina; VD: vas deferens. D: shell maximum diameter; ex/x: specimen/s; H: shell height; HA: aperture width; leg.: legit; m: meter/s; mm: millimeter/s; R2: ribs number on 2 mm of the penultimate whorl; sh: shell/s; WA: aperture height.

RESULTS

Systematics

Classis GASTROPODA Cuvier, 1791
Ordo LITTORINIMORPHA Pchelintsev, 1963
Familia POMATIIDAE Newton, 1891

Tudorella panormitana (Sacchi, 1954)

DISTRIBUTION AND BIOLOGY. Endemic species of the Palermo Mountains, widespread from Trabia in the west to Monte Palmeto in the east (Sacchi, 1954; Alzona, 1971; Lo Brano & Sparacio, 2006; Reitano et al., 2012). This species was reported for the Isola delle Femmine by Sacchi (1954).

Tudorella panormitana is a xeroresistant species typical of limestone soil.

STATUS AND CONSERVATION. *Tudorella panormitana* is Least Concern according to the Categories and Criteria of the IUCN Red List of Threatened Species (IUCN, 2017; Martínez-Ortí, 2017; Neubert et al., 2019).

STUDY AREA. The live specimens were mainly found at the base of the rocks on the northern slope; the shells were found in garrigue areas and in the *Pistacia lentiscus* litter (Figs. 11, 12, 31).

REMARKS. According to Pfenninger et al. (2010), seems that the current distribution of *Tudorella Fischer, 1885* in the Western Mediterranean is due to the fragmentation of the original distribution area that occurred in the late Oligocene and Miocene, and dispersive phenomena that occurred in the late Miocene and Pleistocene. The molecular study of Pfenninger et al. (2010) also highlights the existence of relevant genetic distances between populations of *T. panormitana* and *T. multisulcata* (Potiez et Michaud, 1838) species widespread in the mountains of Trapani and southern Sicily.

Infraclassis PULMONATA Cuvier in Blanville, 1824
 Ordo STYLOMMAТОPHORA A. Schmidt, 1855
 Familia CHONDRINIDAE Steenberg, 1925

Granopupa granum (Draparnaud, 1801)

DISTRIBUTION AND BIOLOGY. European-Mediterranean-Turanian, present throughout Italy.

Xeroresistant and calciphilous species, usually found in rocky and ruderal environments. Common in Sicily in arid areas and Mediterranean scrub.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. A few shells of *G. granum* were found in detritus at the base of outcropping rocks exposed to south-east and partly covered by *Pistacia lentiscus* and *Pennisetum setaceum*.

Familia TRUNCATELLINIDAE Steenberg, 1925

Truncatellina callicratis (Scacchi, 1833)

DISTRIBUTION AND BIOLOGY. European-Mediterranean-Turanian species, widely distributed in the Mediterranean region.

It is common in dry limestone landscapes with herbaceous vegetation and Mediterranean maquis.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. Living specimens of *T. callicratis* have been found only in the *Pistacia lentiscus* litter (Figs. 13, 14, 32).

Familia ENIDAE B.B. Woodward, 1903

Mastus pupa (Linnaeus, 1758)

DISTRIBUTION AND BIOLOGY. Mediterranean. *Mastus pupa* is present in Southern Italy, Sardinia and Sicily (Alzona, 1971; Beckmann, 1990; Manganelli et al., 1995).

It is a thermophilic species, present in a wide variety of habitats.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. This species is common in the

Reserve (Figs. 15, 16, 33). It is more commonly found, both alive and shells, in the south-east slope between the scrub of *Pistacia lentiscus* and *Pennisetum setaceum*, in the litter and under boulders. Also present around the Torre di Fuori and at the base of more exposed rocky outcrops.

Familia FERUSSACIIDAE Bourguignat, 1883

Ceciliooides (Ceciliooides) raphidia sicula
 Beckmann et Falkner, 2008

DISTRIBUTION AND BIOLOGY. *Ceciliooides (Ceciliooides) raphidia raphidia* (Bourguignat, 1856) lives in North-Africa, *C. raphidia sicula* is an endemic subspecies of Sicily (Beckmann & Falkner, 2008).

STATUS AND CONSERVATION. Least Concern (Neubert et al., 2019).

STUDY AREA. Very common with empty shells in the debris found under stones, in crevices, and above all, in the *Pistacia lentiscus* litter (Fig. 34).

REMARKS. The genus *Ceciliooides* A. Féruccac, 1814 comprises endogenous species that usually live buried under stones, between plant roots and on the soil of caves. Beckmann & Falkner (2008) report for the surroundings of Palermo also *C. actoniana* (Benoit, 1862) and *C. rizzeana* (Benoit, 1862).

Ferussacia folliculum (Schröter, 1874)

DISTRIBUTION AND BIOLOGY. Mediterranean. Thermophilic species, inhabiting arid environments with little vegetation cover.

STATUS AND CONSERVATION. Least Concern (Neubert et al., 2019).

STUDY AREA. In the Reserve, *F. folliculum* is very common; both living specimens and empty shells were found under rocks or debris (Figs. 17, 35).

Familia ACHATINIDAE Swainson, 1840

Rumina decollata (Linnaeus, 1758)

DISTRIBUTION AND BIOLOGY. Mediterranean; it is

present throughout the Italian peninsula and the islands. It was accidentally introduced by human activities in many temperate regions. In Central-Northern America to it was employed in biological control against the helcid *Cornu aspersum* (Cowie, 2001).

Rumina decollata is thermophilic and xeroresistant thanks to the secretions of a calcium carbonate epiphragm to close the aperture against body-water evaporation while allowing gas exchange and its habit of burrowing into the ground during the hot season. Its ability to self-fertilization and the eggs with a calcareous casing have contributed to its wide spread. It is omnivorous and even necrophilic. It frequently lives under stones, among organic debris, in dry stone walls and under dead trunks, bushes and shrubs.

STATUS AND CONSERVATION. Least Concern (Neubert et al., 2019).

STUDY AREA. It is quite common, especially around the Torre di Fuori and along the path, even on the *Pistacia lentiscus* litter where it has also been found alive (Figs. 18, 36).

REMARKS. The genus *Rumina* Risso, 1826 is represented in Sicily with two species: *R. saharica* Pallary, 1901 from Marettimo island (Liberto et al., 2012) and *R. decollata*, widespread throughout the island. *Rumina decollata* is also present in almost all the circumsicilian islands (Monterosato, 1892).

DNA-sequence data have suggested that *R. decollata* is a complex of at least seven cryptic phylogenetic species (Prévet et al., 2014) but further studies on a larger number of populations would be needed.

Familia CLAUSILIIDAE J.E. Gray, 1855

Siciliaria leucophryna microinsularis n. ssp.
<https://zoobank.org:act:010DF2E8-A051-4F7D-BC2C-5B63CE8C3BA9>

TYPE MATERIAL. Holotype, Isola delle Femmine (small island near Municipality of Isola delle Femmine, Palermo, Italy), 18.V.2002, leg. I. Sparacio (MCZR) (Fig. 37). Paratypes, all from the type locality: 18.V.2002, 5 exx, leg. I. Sparacio (CS-5803/5); 3.V.2010, 2 exx, leg. I. Sparacio (CS-5804/2); 22.XII.2020, 24 exx., leg. I. Sparacio (CS-5805/24); idem, 38 exx, leg. R. Viviano (CV);

idem, 5 exx., leg. I. Sparacio & R. Viviano (CL-19446–19450); idem, 5 exx., leg. I. Sparacio & R. Viviano (CR); idem, 2 exx., leg. I. Sparacio & R. Viviano (MSNG); idem, 2 exx., leg. I. Sparacio & R. Viviano (MZUF); idem, 2 exx., leg. I. Sparacio & R. Viviano (MHNG); 18.II.2021, 7 exx., leg. I. Sparacio (CS-5806/7, Figs. 38–44); idem, 9 exx., leg. R. Viviano (CV); idem, 2 exx., leg. S. Surdo (CS-5807/2); 01.IV.2021, 10 exx., leg. I. Sparacio (CS-5808/10); idem, 6 exx., leg. R. Viviano & S. Surdo (CV); 27.V.2021, 12 exx., leg. R. Viviano (CV), 1 ex, leg A. Viviano & S. Surdo (CV).

DESCRIPTION OF THE SHELL. Sinistral, fusiform, yellowish, usually decollated with 7–9 slightly convex whorls and robust, spaced and slightly oblique ribs (Figs. 21, 37); these are irregularly arranged in the cervical portion of the last whorl; R2: 4; H: 14–18 mm; D: 4–5.1 mm; HA: 5–5.15 mm; WA: 3.85–3.9 mm; sutures deep, closed umbilicus; basal keel very distinct and revealed; dorsal keel obsolete; rounded aperture, reflected peristome not detached above. Apical whorls, observed only in one damaged specimen (Fig. 40), almost cylindrical: first whorl with smooth surface, second whorl with very fine punctures and very minute and just raised ribs.

On palatum (Fig. 38) there are: a thin sutural plica, the principal plica long and well developed, its internal side protrudes slightly beyond the lunella, upper palatal plica divided into an anterior portion running parallel to principal plica and widely separated from a posterior portion fused to apical end of lunella. Lunella dorso-lateral.

On parietum (Fig. 39) starting from the suture, there are: a parietal lamella that surpasses the spiral lamella, this latter progressively decreasing in height towards the aperture, columellar lamella low, subcolumellar lamella internal, not visible in frontal view. Clausilium (Fig. 41) plough-like with sub-rectangular basal plate, emarginated, rounded sutural angle and straight columellar edge, distal part with an evident incision.

GENITALIA (Figs. 42–44). Vagina (3–3.2 mm) longer than the free oviduct (2.8 mm), bursa copulatrix with a robust copulatory duct (3.3–3.45 mm) shorter than the bursa copulatrix complex (3.1–3.2 mm); bursa copulatrix is oval-elongated, pointed at the apex; diverticulum of the bursa copulatrix (6–6.3 mm) longer than bursa copulatrix complex; vas deferent long and slender, entering the apical portion

of epiphallus; epiphallus (4–4.3 mm) divided by point of insertion of robust penial retractor muscle into sub-rectangular distal portion, and elongated proximal portion with an evident epiphallar ring where start the penis; penis (2.9–3.2 mm) wider than epiphallus, sub-cylindrical in shape.

In the inner genitalia, the penis shows two longitudinal raised pleats that occupy almost the whole penial lumen; penial pseudopapilla is elongated (almost 1/3 of the total length of penis) with some thin longitudinal grooves on its surface. The penis-epiphallus transition shows a first distal annular pad and a second proximal annular pad from which the penial pseudopapilla and the epiphallar pleats originate. Inner wall of the vagina with irregular and little transverse-oblique pleats in the prossimal portion, and with very thin and irregular thin longitudinal pleats in the distal portion.

BODY. Animal yellow-brown; skin tubercles oval-elongated browner than the body; upper tentacles rather short, cylindro-conical, with black eyes; foot with sole paler than body (Fig. 22).

DISTRIBUTION AND BIOLOGY. *Siciliaria leucophryna leucophryna* (L. Pfeiffer, 1862) is a calciphilous species endemic of Sicily; it is limited to the surroundings of Palermo (Sferracavallo) to the East and Municipality of Isola delle Femmine to the West. *Siciliaria leucophryna microinsularis* n. ssp. lives only on some calcareous rocks of the island of Isola delle Femmine; several specimens was found also in the *Pistacia lentiscus* litter.

ETYMOLOGY. The name of this new subspecies derives from the locality where it lives: a small territory on a small island (Isola delle Femmine or Isola di Fuori).

STATUS AND CONSERVATION. *Siciliaria leucophryna leucophryna* is Endangered species according to De Mattia (2017) and Neubert et al. (2019). *Siciliaria leucophryna microinsularis* n. ssp. must be classified as Critically Endangered (CR) due to the very restricted area in which it lives.

OTHER EXAMINED MATERIAL. *Siciliaria leucophryna leucophryna*: Italy, Sicily, Palermo, Sferracavallo: Grotta Conza, 18.I.1981, 6 exx, leg. I. Sparacio (CS-5801/6); idem, 36, exx, 11.IX.2003 (CS-5802/36); idem, 3 exx, 27.V.2012, leg. R. Viviano (CV); idem, 35 exx, 20.VII.2005, leg. A. Reitano (CR); idem, 12 exx, 5.XII.2008, leg. A. Reitano (CR);

idem, 38°11'14"N, 13°16'39"E, 200 m, 27.V.2012, 3 exx, 6 shells (CL 11736–11744); idem, 245 m, legit Viviano R., 16.X.2016, 3 exx (CL 17308–17310); idem, 38°11'14"N, 13°16'42"E, 190 m, legit Reitano A., 2011, 6 exx, 8 shells (CL 17365–17391).

COMPARATIVE NOTES. *Siciliaria leucophryna* has been confused with *S. eminens* (Schmidt, 1868), particularly by Boettger (1879) and Benoit (1882), however Nordsieck (2002) specified its distribution area in the neighbourhoods of Sferracavallo and selected a lectotype (Senckenberg Museum, Frankfurt 67478, coll. O. Boettger ex-Dohrn ex-L. Pfeiffer) (see also Reitano et al., 2012).

Siciliaria leucophryna microinsularis n. ssp. is morphologically different from topotypical specimens of *S. leucophryna leucophryna* (Sferracavallo, Grotta Conza) due to its smaller size (H: 18–22 mm in *S. leucophryna*), lighter color, anterior upper palatal plica widely separated from posterior upper palatal plica (little separated or connected in *S. leucophryna leucophryna*), first duct of the bursa copulatrix shorter than in *S. leucophryna leucophryna*, penial pseudopapilla longer and inner walls of the vagina with transverse-oblique pleats and some very thin longitudinal pleats in the distal portion (only transverse-oblique pleats in *S. leucophryna leucophryna*).

Familia PRISTILOMATIDAE Cockerell, 1891

Vitre a subrimata (Reinhardt, 1871)

DISTRIBUTION AND BIOLOGY. Species with European-Mediterranean distribution spreading throughout Italy. *Vitre a subrimata* comprises a complex of populations which differ by the structure of flabelliiform appendices of the inner wall of the proximal penis and therefore needing a modern revision (Manganelli et al., 1995; Ferreri et al., 2005).

Vitre a subrimata inhabits mainly natural environments, usually cavities in soil, or under partly concealed rocks or boulders.

STATUS AND CONSERVATION. Least Concern (Neubert et al., 2019).

STUDY AREA. Only empty shells of *V. subrimata* were found by sieving debris collected under stones, in crevices, and above all, in the *Pistacia lentiscus* litter (Fig. 45).

Familia AGRIOLIMACIDAE H. Wagner, 1935

Deroberas panormitanum (Lessona et Pollonera, 1882)

DISTRIBUTION AND BIOLOGY. European-Mediterranean and some extra-European countries. A common and widespread species, anthropophilic and ubiquitous.

D. panormitanum is very common in Sicily, where it lives in a wide range of natural and anthropized environments.

STATUS AND CONSERVATION. Least Concern (Rowson, 2017; Neubert et al., 2019).

STUDY AREA. Living specimens of this species were found mainly on the north side of the island and around Torre di Fuori, under stones (Figs. 19, 20), and on the east side some limacella were collected by sieving the soil.

REMARKS. *Deroberas panormitanum* is considered a species variable in external colour, morphology and shape of the genitalia (Giusti, 1973; 1976; Giusti & Manganelli, 1990; Giusti et al., 1995; Wiktor, 2000; Reise et al., 2011).

Familia TRISSEXODONTIDAE H. Nordsieck, 1987

Caracollina (Caracollina) lenticula (Michaud, 1831)

DISTRIBUTION AND BIOLOGY. Mediterranean distribution. In Sicily, it is very common from a few meters above sea level up to medium altitudes, under stones, in the dune system and in the compact hilly terrain.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. *Caracollina lenticula*, together with *Eobania vermiculata* (O.F. Müller, 1774) and *Ferussacia folliculum*, is one of the most frequent species on the island (Fig. 23, 24, 46). Living specimens and empty shells of *C. lenticula* were found in the *Pistacia lentiscus* litter and under stones.

Familia GEOMITRIDAE C.R. Boettger, 1909

Cochlicella acuta (O.F. Müller, 1774)

DISTRIBUTION AND BIOLOGY. Mediterranean. It is reported for almost all regions of central-southern Italy, Sicily and Sardinia (Alzona, 1971; Cossignani & Cossignani, 1995, 2020; Manganelli et al., 1995).

In Sicily, it is very common from a few meters above sea level up to medium altitudes.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. During these investigations, only one living young specimen was found among the boulders positioned below the reserve billboard.

Xerotricha conspurcata (Draparnaud, 1801)

DISTRIBUTION AND BIOLOGY. Mediterranean, reported in Italy for peninsular regions, Sicily and Sardinia (Alzona, 1971; Cossignani & Cossignani, 1995, 2020; Manganelli et al., 1995).

It is very common in Sicily under stones and debris from various coastal areas to medium altitudes. It lives in natural or antropized environments.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. In the Reserve, it is a common species, especially around the Torre di Fuori, where it lives in the macerate and under vegetal detritus, and in the litter of *Pistacia lentiscus* and *Pennisetum setaceum* (Figs. 25, 26, 47).

Xerotricha apicina (Lamarck, 1822)

DISTRIBUTION AND BIOLOGY. Mediterranean distribution, reported in Italy along the Tyrrhenian, southern and island regions (Alzona, 1971; Cossignani & Cossignani, 1995, 2020; Manganelli et al., 1995).

This species is very common in Sicily under stones and debris from coastal areas to medium altitudes, in natural or antropized environments.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. Numerous shells were collected only in the surroundings of Torre di Fuori, under limestone boulders, in the soil and under the leaf

blades of prostrate herbaceous plants. Only one living specimen was found in the soil at the base of outcropping rocks. Towards the end of May they estivate burying themselves and closing the aperture with a thin white, paper-like epiphramgm (Fig. 27).

Cernuella (Cernuella) cfr. cisalpina (Rossmässler, 1837)

DISTRIBUTION AND BIOLOGY. European-Mediterranean distribution (Manganelli & Giusti, 1987; Manganelli et al., 1995).

In Sicily, this species is common, from back dunes up to medium altitudes, in natural and anthropized environments.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. Few shells were sampled scattered on the island, including the surroundings of the tower and in the litter of *Pistacia lentiscus*, always without the periostracum.

Cernuella (Cernuella) cfr. virgata (Da Costa, 1778)

DISTRIBUTION AND BIOLOGY. European-Mediterranean distribution (Manganelli & Giusti, 1987; Manganelli et al., 1995).

Thermophilic and xeroresistant, it is widespread in Sicily, at low and medium altitudes, in different natural environments, even degraded and anthropized, often in numerous colonies on grasses and shrubs.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. In the Reserve, this species is quite common in grassland. It differs from the previous species for a bigger and more rounded shell and a less wide umbilicus (Figs. 28, 48).

Trochoidea (Trochoidea) caroni (Deshayes, 1832)

DISTRIBUTION AND BIOLOGY. Western-Mediterranean (Maio et al., 2013).

Relatively widespread in Sicily, from coastal areas to medium altitudes, especially in grassy habitats.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. Uncommon in the reserve. Some shells have been found in different points of the island, both near the Torre di Fuori, along the coast and in the *Pistacia lentiscus* litter (Fig. 49).

REMARKS. *Trochoidea (Trochoidea) caroni* (Deshayes, 1832), with *T. (T.) elegans* (Gmelin, 1791) and *T. (T.) trochlea* (Pfeiffer, 1846), belong to a group of species which need a modern systematic review. In Sicily, *Trochoidea (T.) caroni* shows populations which differ in shape and size of the shell. The population we found in the Isola delle Femmine is morphologically similar to the typical material from Palermo (see Maio et al., 2013).

Familia CANARIELLIDAE Schileyko, 1991

Schileykiella reinae (Pfeiffer, 1856)

DISTRIBUTION AND BIOLOGY. Endemic species of western Sicily with fragmented distribution.

Schileykiella reinae is a chalcophilous and hygrophilous species present in forest environments, Mediterranean scrub, at the base of limestone cliffs, or under rocks and debris.

STUDY AREA. A fair number of shells of this species were collected exclusively in the *Pistacia lentiscus* litter near outcropping rocks (Fig. 50).

STATUS AND CONSERVATION. Near Threatened (Cuttelod et al., 2011; Neubert et al., 2019).

REMARKS. The genus *Schileykiella* Manganelli, Sparacio et Giusti, 1989 includes three other species: *S. parlatoris* (Bivona, 1839), widespread in Sicily and Malta, *S. bodoni* Cianfanelli, Manganelli et Giusti, 2004, known only for Marettimo island (Cianfanelli et al., 2004) and *S. mariarosariae* R. Viviano, A. Viviano, Liberto, Reitano & Sparacio, 2019 known only from Mount Pecoraro, Cinisi near Palermo (Viviano R. et al., 2019).

Familia HELICIDAE Rafinesque, 1815

Murella platychela platychela (Menke, 1830)

DISTRIBUTION AND BIOLOGY. Endemic species of

the North-Western Sicily, with several subspecies; the nominal subspecies was described from Monte Cuccio (Pfeiffer, 1931), a few kilometers South of the area covered by this study.

It is strictly calciphilous species and inhabits rocky sites.

STATUS AND CONSERVATION. Data Deficient following Neubert et al. (2019).

STUDY AREA. *Murella platychela platychela* was found on the rocky walls of the Reserve, particularly in the northern slope (Fig. 51).

***Theba pisana* (O.F. Müller, 1774)**

DISTRIBUTION AND BIOLOGY. Mediterranean distribution extended to Macaronesia and to the North African and European Atlantic coasts (Gittenberger & Ripken, 1987), passively diffused in other extra-European countries (Giusti et al., 1995). In Italy, it is present for almost all of peninsular Italy, Sicily and Sardinia (Alzona, 1971; Manganelli et al., 1995).

It is a thermophilic and photophilic species, typically linked to the dune system but also present in Sicily in more inland localities, at low altitudes, where it is found on various herbs and shrubs, often in large populations.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. Few live specimens and numerous fresh died shells have been found, both around the Torre di Fuori and along the coast (Figs. 29, 52).

***Eobania vermiculata* (O.F. Müller, 1774)**

DISTRIBUTION AND BIOLOGY. Mediterranean. Widespread by man in many non-Mediterranean countries.

It is thermophilic, common in many types of environments, both natural and anthropized, from a few meters above sea level up to medium altitudes.

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. Living specimens of *E. vermiculata* have been found in the reserve under rocks or in limestone walls. In May, numerous young specimens were found adhering on the stems

of *Pennisetum setaceum* and other plants (Figs. 30, 53, 54).

REMARKS. *Eobania vermiculata* is present in all the circumsicilian islands with more or less differentiated populations (Benoit L., 1857–1862, 1875, 1882; Monterosato, 1892; Alzona, 1971)

***Cantareus apertus* (Born, 1778)**

DISTRIBUTION AND BIOLOGY. Species with Mediterranean distribution, present in almost all the Italian peninsula, Sicily and Sardinia.

It is thermophilic, common in open, arid, even anthropized and degraded environments, at low and medium altitudes. In Summer it estivates, under the ground, closing the aperture of the shell with a robust white and convex epiphragm.

STUDY AREA. *Cantareus apertus* has been found in the prairie and in the scrub with *Pistacia lentiscus* and *Pennisetum setaceum*, in the area along the coast (Fig. 55).

STATUS AND CONSERVATION. Least Concern (Cuttelod et al., 2011; Neubert et al., 2019).

REMARKS. The genus *Cantareus* Risso, 1826 has included only this species for many years. Following Bouaziz-Yahiatene et al. (2019), mainly based on molecular data, *C. subapertus* (Ancey, 1893) and *C. koraegaelius* (Bourguignat in Locard, 1882) from Algeria are also attributed to this genus.

Cantareus apertus with *Eobania vermiculata* and *Theba pisana* are the best known edible molluscs in the Sicilian tradition (De Stefani, 1923; Pusateri, 2016; Sparacio, 2020). Local witnesses tell how, in the past, the islet was used for the collection of these shells for food purposes. The invasion of the brown rat (*Rattus norvegicus*) before and the presence of the yellow-legged gull (*Larus michahellis*) now strongly affected the populations of *C. apertus* and *T. pisana*.

***Ercatella mazzullii* (De Cristofori & Jan, 1832)**

DISTRIBUTION AND BIOLOGY. Endemic species of the Palermo Mountains, widespread from Monte Pellegrino (Palermo) in the east to Monte Palmeto (Terrasini) in the west (Colomba et al., 2011; 2015).

The species of the genus *Ercatella* Monterosato, 1894 are calciphilous and saxicavous (see Colomba

et al., 2011 and cited bibliography; Hausdorf et al., 2020).

STATUS AND CONSERVATION. Endangered (Cuttelod et al., 2011; Neubert et al., 2019).

STUDY AREA. The species is quite rare and localized within the reserve, on the limestone walls. The only fresh died shell (Fig. 56) would seem to belong to the island population, while other very damaged shells would have been found near seagull nests, most likely preyed in the neighboring territories. The peculiar groupings of tunnels where *E. mazzullii* lives are present in various rocks of the Isola delle Femmine but its presence in the Reserve has to be confirmed (Fig. 57).

REMARKS. In Sicily, the genus *Ercatella* includes two other species *E. cephalaeeditana* (Giannuzzi-Savelli, Oliva et Sparacio, 1986), endemic of the Rocca of Cefalù, and *E. insolida* (Monterosato, 1892), widespread in the mountains of Trapani. A new species endemic to the island of Crete has recently been described: *E. cretense* Hausdorf, Bamberger et Walther, 2020 (Hausdorf et al., 2020).

CONSIDERATIONS AND CONCLUSIONS

This study has allowed us to reach a good state of knowledge on the malacological biodiversity of the Isola delle Femmine, but further investigations are recommended. This biotope was little known until now in the malacological literature and reported only by Sacchi (1954) for the presence of *Tudorella panormitana*.

A total of 23 species of terrestrial molluscs have been recorded in this study. They are concentrated in three characteristic environments of this small island: under stones and debris in the open areas and among the ruins around the Torre di Fuori, in the litter of *Pistacia lentiscus* and in the limestone walls. The most widespread and abundant species are *Truncatellina callicratis* (in *Pistacia lentiscus* litter), *Ferrussacia folliculum* and *Caracollina lenticula* (which are often found together, under stones), *Eobania vermiculata* (almost everywhere).

Judging by the presence of the empty shells, *Cecilioides raphidia sicula* and *Vitrearia cfr. Subrimata* are also quite common.

Less numerous but fairly stable populations are those of *Tudorella panormitana*, *Mastus pupa*, *Rumina decollata*, *Deroceras panormitanum*, *Xerotricha conspurcata*, *X. apicina*, *Cernuella cfr. virgata*, *Theba pisana* and *Cantareus apertus*. The only exclusive endemism of the island appears to be very localized: *Siciliaria leucophrina microinsularis* n. ssp. Numerous fresh died shells of *Murella platychela* have been found on the limestone walls of the northern slope, while the presence of a living population of *Ercatella mazzullii* needs confirmation.

Another 4 species have not been included to date, among the land molluscs living on Isola delle Femmine because they were found only with single empty shells of probable passive introduction: *Cecilioides* sp., *Hohenwartiana aradasiana* (Benoit, 1862), *Murella globularis* (Philippi, 1836) and *M. muralis* (O.F. Müller, 1774).

Mediterranean is the predominant chorotype (11 species equal to 48%), extended to Macaronesia and Ocean Atlantic coasts (1 species) or limited to the western area (1 species). The European-Mediterranean chorotype has 6 species (26%) of which 2 species extended to the Turanic area. Sicilian endemic species are in all 5 (22%) and only one taxon is endemic to this islet (4%).

In Table 1 the check list of land molluscs from Isola delle Femmine is compared with that from Grotta Conza Reserve, Sferracavallo (Reitano et al., 2012) and that of the coastal area of the municipality of Isola delle Femmine (personal data). In the Grotta Conza Reserve are recorded 41 species of land molluscs, thanks to the presence of a relatively intact and diversified environment. The coastal area in the municipality of Isola delle Femmine, although characterized by a heavy anthropic impact with some natural environments that have now disappeared, record 34 species strongly fragmented in the territory and isolated in relict environments.

The 23 species found on the Isola delle Femmine are also present in the neighbors localities mentioned, as can be seen from the direct comparison in table 1. The total number of species registered in the Isola delle Femmine is lower than these locality but, in relation to the condition of insularity, the reduced territorial extension and the environmental difficulties constitute an important and peculiar insular malacocenosis.

Almost all of these species, according to the IUCN (2017) criteria applied by Cuttelod et al. (2011) and Neubert et al. (2019), are Least Concern. *Schileykiella reinae* is Near Threatened species, *Murella platychela platychela* is Data Deficient, and *Ercetella mazzullii* are classified as Endangered.

Siciliaria leucophryna microinsularis n. ssp. was listed by us as Critically Endangered.

Our actual knowledge on the history of animal populations of Isola delle Femmine does not enable to understand the real effects on the fauna and flora of this island of the anthropic impact. Indeed, the alteration of the original vegetation, the introduction of alien species such as brown rat or natural environmental effect of local seagull

colony, presumably has led to the extinction of some taxa and to the rarefaction of others.

Present and future work on the distribution and abundance of animal populations such may be used to observe trends and assess threats to conservation, especially in the cases of endemic or rare species (Lo Cascio & Pasta, 2012).

All the species of land molluscs present on the Isola delle Femmine, in relation to the delicate balance reached by these populations today, should be regularly monitored and subjected to a special surveillance and protection program. Finally, it is also necessary to investigate the identity of some invertebrates to understand better the biogeographical importance and biological heritage of this small island.

ACKNOWLEDGEMENTS

We want to thank very much Vincenzo Di Dio, the director of the Reserve “Isola delle Femmine” (palermo, Italy) who made it possible to collect the material for this study and facilitated all phases such as use of the boat to reach the island, sampling, etc. Furthermore, he has undertaken with the authors constructive debates on the status of knowledge of Reserve. Activity carried out within the convention between the SAAF department and Lipu (“Check list delle specie di invertebrati, vertebrati ed individuazione delle migliori tecniche di propagazione del Lentisco (*Pistacia lentiscus*) presenti nell’Isola delle Femmine, Palermo”, project head Tommaso La Mantia, Professor at the University of Palermo). We also are indebted with Antonino Barbera (Castelvetrano, Italy) and Marcello Romano (Capaci, Italy) who authorized the use of their photographs.
