

Contribution to the knowledge of beetles (Insecta Coleoptera) of some protected areas of Apulia, Basilicata and Calabria (Italy)

Fernando Angelini

Via De Reggio 142, 72021 Francavilla Fontana, Brindisi, Italy; email: angelini_fernando@libero.it

ABSTRACT

The lists of Coleoptera published by the author between 1986 and 1996 concerning the following protected areas from southern Italy are updated: Gargano Promontory, Policoro Wood, Pantano Lake of Pignola, Pollino Massif and Sila Plateau. Data is integrated with subsequent collections of the writer and with bibliographic citations of other authors. With the same criteria the species of further three areas are also listed: Mount Vulture-Monticchio Lakes, Central Lucan Apennines and Aspromonte. A total of 5,130 taxa were recorded for the eight surveyed National or Regional Parks, which are located in Apulia, Basilicata and Calabria regions (Italy). Of these species, 472 are endemic to the Italian territory. The saproxylic species amount to 1,115, their related IUCN category is referred to and an interpretation of the emerging data is suggested. A chronology of the entomological researches carried out in the past has been reconstructed, moreover description of main features and geographical boundaries of the treated sites are provided. All taxa subject of this study are listed in taxonomic order with indication of the areas where their presence occurs and specifying the data source. The total number of species for each family is evaluated area by area and the data on the most representative of Coleoptera families are briefly commented, with remarks on the current state of research.

KEY WORDS

Biodiversity; Coleoptera; National Parks; southern Italy; species.

Received 10.10.2019; accepted 21.02.2020; published online 16.03.2020

INTRODUCTION

The realization of this work stems from the need to update, in the taxonomy and nomenclature, several catalogues on southern Italy Coleoptera published by the author in the decade 1986-1996: Coleottero fauna del Massiccio del Pollino (Angelini, 1986), Coleottero fauna del bosco di Policoro (Angelini & Montemurro, 1986), Coleottero fauna del Promontorio del Gargano (Angelini, 1987), Coleottero fauna dell'Altopiano della Sila (Angelini, 1991) and Coleottero fauna della Riserva Naturale WWF Lago Pantano di Pignola (Angelini, 1996).

The research carried out in the following years by the author has besides produced a significant amount of unpublished data, which here go to integrate those previously published. Likewise, to offer an overview as accurate and complete as possible of the current state of knowledge on the Coleoptera in these areas, all the species and data reported by other authors in the vast bibliography (annexed) have been added.

It has been decided to expand the portion of territory examined in the previous catalogues to include the Park of the Mount Vulture-Monticchio Lakes, the Central Lucan Apennines and the Aspro-

monte since for these areas the amount of data collected over the years is significant and at the same time there is a body of literature that dates back to the first entomological explorations of Southern Italy, going back to the last quarter of XVIII century. Map of figure 1 shows the general location of all the study areas.

For the Gargano Promontory, data from Holldaus (1911), previously excluded by Angelini (1987), are also included.

It is necessary to present the unpublished or bibliographic data in the form of a table rather than provide a full list with accurate information on the collection localities since this solution, although more appropriate, would require a remarkably more voluminous contribution; a similar update is underway, with comprehensive detail of all the localities, bibliographic references and status changes that have occurred over time, to be published exclusively online.

The coleopterological researches in Apulia, Basilicata and Calabria

The extreme south of Italy is a reservoir of great biodiversity and of a fauna with a rather different composition than the rest of the Peninsula. Entomo-

Figure 1. Study areas: in black, the location of the eight sites in southern Italy covered by this study.

logically, this territory suffered greatly during the 19th century due to the substantial lack of naturalists native to these regions and for the difficulty of connections by land (Salfi, 1963: 4) because of the local wilderness; it is not a coincidence that the history that will be exposed is clearly different from that of neighboring Sicily (Romano, 2006).

Only in the 20th century, studies on entomofauna have become more systematic, sometimes promoted by Italian universities and museums to acquire valuable study material.

A substantial contribution came from the author's personal researches, being himself favored by residing in Apulia and thus being able to more easily and frequently explore the target regions of this work, and from the many colleagues and friends entomologists with whom he shared fruitful hikes over the years.

The following is a chronicle of the explorations that involved these areas.

1783. The earlier research of which we know about in southern Italy are conducted in Aspromonte (Calabria ulteriore) in 1783 by Giulio Candida and Giuseppe Stefanelli and published by Vincenzo Petagna (1787), which lists 239 species of collected insects. It should be emphasized that this publication was a great success at the time so that the first print, which took place in 1786 and has not been possible to obtain, was followed by others including that of 1787 mentioned in the bibliography and most frequently cited.

1826. Luigi Petagna, Giovanni Terrone and Michele Tenore from 3 to 16 July make a botanical expedition from Naples to Cosenza, visit Monte Sirino and Pollino and mention 4 species of Coleoptera.

1827. Oronzo Gabriele Costa visits the Aspromonte together with Giovanni Gussone in the month of July (Costa A., 1863) and the list of vertebrates and arthropods they found is published 12 years later (Costa O.G., 1839), although the related report is read at the Royal Academy of Sciences the following year.

1851. Christian Suffrian (1851: 79) describes *Chrysolina interstincta* based on two specimens coming respectively from Sicily and Calabria and collected by Ludwig Parreyss (Daccordi & Ruffo, 2005: 121, teste Bourdonné); no other data was

found concerning the research carried out by Parreyss in Calabria.

1859. Achille Costa visits Sila and Aspromonte (Costa A., 1881: 1). Four years later he publishes the data about Aspromonte (Costa A., 1863) listing 577 Coleoptera species, which include those previously mentioned by Petagna (1787).

1870–1875. Giovanni Battista Adami, A. Stefanini, Filippo Fanzago, Guelfo Cavanna and L. Panato presumably perform entomological research in Calabria in these years and a first list (devoid of collecting sites) of 300 species of Coleoptera is published by Bertolini (1876).

1876. Achille Costa from July 11th to September 12th of 1876 visits Sila, the surroundings of Tirolio and Cirò and makes known the results of his research five years later (Costa A., 1881: 45–51).

1876. Guelfo Cavanna and other naturalists visit the Aspromonte in the months of May and June and their material is studied by various specialists, but the results are not divulged.

1878. Flaminio Baudi di Selve conducts researches in Calabria: *Omoglymmius germari* (Ganglbauer, 1891) in Mazzei et al. (2019).

1880. Antonio Biondi, Cesare Caroti and Guelfo Cavanna between the 8th and 16th of July 1880 carry out research in Rionero and Mount Vulture and between 24th and 28th of July the same year on Pollino. The results are released by various specialists and the whole list of collected Coleoptera is published by Baudi, Piccioli & Cavanna (1882). Cavanna (1882) also publishes a detailed report about this mission.

1881. (April), 1883 (September), 1884 (May), 1887 (August) Andrea Fiori is in Calabria (in 1884 and 1887 with Flaminio Baudi di Selve); dates of the last three trips are taken from one of his works (Fiori, 1894: 87); many data are disclosed in various papers both by Fiori and Baudi. Most of the citations found in Luigioni (1929) sub “Cal” are taken from these research, and secondarily from the publications mentioned above and a few others that follow.

1887. Andrea Fiori in August visits Sila (Fiori, 1894) and Gargano (Fiori, 1914b); only some of the data are made known in scattered works.

1896. Achille Costa visits Pollino Massif (Salfi,

1963: 19 and Ruffo & Vigna Taglianti, 1988: 13) but does not publish the relevant data.

1905. Gustav Paganetti-Hummel visits Aspromonte for a long time; from one of his papers (Paganetti-Hummel, 1910) can be deduced that he collected in the following periods and localities: April-May in Gerace, Antonimina and Ciminà, from May to the beginning of August in Santa Cristina, Sant’Eufemia and Aspromonte. It is known that a manuscript exists which lists, with collecting localities, the species found in Aspromonte by Paganetti-Hummel (Magistretti, 1960: 111), but unfortunately it was not possible to trace it.

1906. Giacomo Cecconi visits Tremiti Islands between 15 and 25 of February and from 25 of May for a few days. The material collected is published by him two years later (Cecconi, 1908).

1906–1907. Karl Holdhaus visits Gargano from 10 to 30 of May in 1906 accompanied by Hamilkar Stolz and later from 3 to 18 April 1907 together with Alfred Kniž and Moritz Hilf. The latter stayed until the 20th of June to collect Coleoptera on behalf of Otto Leonhard. The results of these researches are published four years later (Holdhaus, 1911).

1909 and 1910. Alfredo Andreini carries out long researches in Basilicata in the surroundings of Latronico and Maratea; from examination of his finds, mentioned in many publications as well as from the direct study of specimens he collected and are now kept in the Dodero collection at Genoa (Poggi i.l.), it is possible to establish that he stayed there from April 21 to September 20 of 1909; instead for the year 1910 the timespan of its permanence is not possible to ascertain.

1911, 1912 and 1913. Andrea Fiori visits Mount Vulture in the month of May 1911 (Ruffo & Vigna Taglianti, 1988: 15). From 15th of April to 4th of June 1912 he makes researches in Calabria and Sicily (Fiori 1915a and 1915b). In 1913 he goes on Gargano (Fiori, 1914b, 1915a). Only a few individual findings are published in the above mentioned works.

1913. Adolfo Falzoni explores Sila in the month of June (Fiori, 1914a: 18).

1921. Andrea Fiori in August visits Sila: *Clinidium canaliculatum* (O.G. Costa, 1839) in Mazzei et al., 2019).

1923. Giuseppe Müller visits Mount Vulture (Ruffo & Vigna Taglianti, 1988: 15).

1925. Arturo Schatzmayr visits Mount Vulture in May (Schatzmayr, 1926: 145, sub *Oedemera subulata* Olivier, 1790 = *Oedemera physica* (Scopoli, 1763)).

1926. Jaroslav Štokrán searches the Gargano in June. A list of species not previously mentioned by Holdhaus (1911) is published by Roubal (1932).

1933. An examination of Zombori's work (1984) shows that Agostino Dodero collected beetles in Sila at Camigliatello from 27 May to 23 August 1933; further data related to Cosenza and San Pietro in Guarano are deduced from the publications of Poggi (2009) and Liberti & Poggi (2018). Reference to his findings is also present in papers by other authors.

1933. Arturo Schatzmayr and Carl Koch visit Pollino in July (Tassi, 1966a: 1 and Magistretti 1955: 1); only three contributions are published on this mission (Koch, 1933a, Koch, 1933b and Wittmer, 1935).

1934, 1937 and 1940. Alessandro Ghigi explores Gargano in August 1934, then in 1937 (unknown period) and again, together with Francesco Pio Pomini, in the second half of April. Between the end of May and 5 June 1940 both of them, besides Gargano, also visit the Tremiti Islands. The results are published by Gridelli (1949b).

1939. Lars Brundin & Thure Palm visit Pollino in June and in a short note several species of Coleoptera are reported (Palm, 1939). The Curculionidae collected in this expedition are treated by Magnano (1957a), and Cerambycidae by Tassi (1966a). Various data are disclosed in works by other authors, including the description of some new species (Nyholm, 1948).

1939. Edgardo Moltoni from June 25 to July 14 collects in Sila and results are published by Schatzmayr (1941 and 1943).

1941–1945. Alessandro Focarile in July 1941 and, with Giovanni Mariani, in April 1942 is on Mount Vulture; between 5 September 1943 and 10 April 1945 he carries out research in various places in Apulia and Basilicata including Mount Vulture and Pollino Massif (Focarile, 1959: 18). The results

of these researches were only published in small part by different authors.

1948. Giovanni Binaghi visits Gargano in the spring; only a few of these data are published (Binaghi, 1948).

1948, 1949, 1950 and 1957. Sandro Ruffo, Edoardo Gridelli, Antonio Giordani Soika, Mario Magistretti and Angelo Pasa go to Gargano, Tremiti Islands, Murge and Salento as part of a research on Apulian fauna promoted by Umberto D'Ancona of the Institute of Adriatic Studies (Gridelli, 1949b: 148; Magistretti, 1966: 8 and Ruffo & Vigna Taglianti, 1988: 21). The results are published by Gridelli (1949a, 1949b and 1950), by Ruffo (1955) as well as by about fifteen Italian and foreign specialists in the journal "Memorie di Biogeografia Adriatica" (1950–1962) (Ruffo & Vigna Taglianti, 1988: 21).

1950. Giovanni Binaghi in May is in Sila and in Aspromonte, only some data is published in various works.

1950, 1951 and 1953. Marcello La Greca, Michele Sarà and R. Capaldo (7 July–10 August 1950), Sandro Ruffo, Angelo Pasa and Livio Tamagnini (10–23 June 1951 and 12–24 June 1953) carry out a series of research campaigns on Pollino promoted by Naples University. The results are published between 1950 and 1966 in thirty-two memoirs (Salfi, 1951; Ruffo & Vigna Taglianti, 1988: 21) seventeen of which dedicated to Coleoptera.

1955. Guido Grandi promotes a research campaign for the Institute of Entomology of Bologna University at the Umbra Forest (Gargano). Searches begin on July the 4th and last for about one month; in addition to Grandi himself, Maria Matilde Principi, Giorgio Fiori, Egidio Mellini and Dante Faggioli also take part. The first results are published by Faggioli (1955); the researches conducted are illustrated by Grandi (1956).

1955. Marcello La Greca visits the Tremiti Islands as part of a research project promoted by the Institute of Zoology and Comparative Anatomy of Bari University.

1956–1958. Alessandro Focarile and Giovanni Mariani in these years undertake coleopterological research in 23 sites along the Ionian shorelines of Apulia, Basilicata and Calabria; they do sampling in Policoro Wood on May 27–29 of 1956, June 9 of

1957 and May 24 of 1958. The outcomes of these researches are illustrated in a series of eighteen works released between 1959 and 1979.

1957, 1958, 1963 and 1966. As part of a research project on Apennine fauna promoted by the Civic Museum of Natural History of Verona and coordinated by Sandro Ruffo (started in 1954 with a mission on the Sibillini Mountains), in Aspromonte six expeditions made up of a total of nine members are performed: in May and July 1957, June and August 1958, August 1963, October 1966 (Magistretti & Ruffo, 1969: 388). The results for 16 families are illustrated in eight papers.

1957. Anna and Mario Magistretti, Angelo Pasa, Sandro Ruffo and Livio Tamanini visit Policoro Wood in May (Magistretti & Ruffo, 1969: 387); individual data are published in many papers.

1960. Anna and Mario Magistretti, Angelo Pasa, Sandro Ruffo and Livio Tamanini visit Mount Vulture and the Monticchio Lakes in June (Magistretti & Ruffo, 1969: 387); only single data are published in several works.

1960. Some Roman entomologists, stimulated by Frederick Hartig, go exploring Mount Vulture (Ruffo & Vigna Taglianti, 1988: 15).

1960, 1961, 1962 and 1967. As part of the research on Apennine fauna promoted by the Civic Museum of Natural History of Verona, five missions carried out by a total of seven members visit Sila, the Coastal Chain and Serre Calabre: in June and August 1960, August 1961, August 1962, July 1967 (Magistretti & Ruffo, 1969: 388). The results concerning 12 families of Coleoptera are published in five papers.

1960, 1961, 1962 and 1963. Giorgio Marcuzzi conducts his research in Apulia (comprehensive of Gargano and the Tremiti islands, including Pianosa) and in Basilicata's province of Matera. The results are shown in the works of Marcuzzi (1962) and Marcuzzi & Lafisca Turchetto (1977).

1961. Walter Liebmann visits Aspromonte (Mangano, 1964: 107) but the results do not appear to have been published.

1962. Giovanni Sichel and his colleagues go to Aspromonte (Tassi, 1966: 622) but the outcome of their research is not known.

1963, 1964 and 1967. As part of the research on Apennine fauna promoted by the Civic Museum of Natural History of Verona, four missions composed by a total of five members visit Apulia (Gargano, Murge, Terra d'Otranto) and Basilicata (Matera): in September 1963, June 1964, May and September 1967. Results are partially published in many papers. Just Magistretti (1966) releases data about Carabidae on the basis of all the specimens collected in Apulia in the overall expedition period.

1963. Gunnar Dahlgren from June 27th to July 7th visits Lorica in Sila by himself (from June 9th to June 26th he explores other Calabrian sites: Paola, Rogliano, Cosenza and Castiglione) and the results are published (Dahlgren, 1964).

1964. A series of researches on the Central Lucan Apennines, Mount Vulture, Pollino and Policoro is begun by numerous members of the Roman Association of Entomology (Fabio and Mario Cassola, Franco Tassi, Silvio Bruno, Vincenzo Vomero, Gianni Gobbi, Giuseppe Maria Carpaneto, Franco Marozzini, Mario and Giuseppe Pinzari, Francesco Sacco, Paolo Marcello Brignoli, Walter Rossi, Paolo Audisio, Enzo Colonnelli) (Gobbi, 1971a: 28) but only a small part of the enormous amount of data collected is published (Gobbi, 1971a, 1973a, 2018; Colonnelli, 1974a; Gobbi & Piattella, 2008).

1965, 1968, 1970 e 1972. Giovanni Binaghi, Italo Bucciarelli, Alessandro Focarile, Giovanni Mariani, Giuseppe Meggiolaro and Carlalberto Ravizza visit Mount Sirino in the Central Lucan Apennines; only a contribution on the Carabids is presented by Ravizza (1973) as a whole, while the remaining data are individually published in scattered works.

1965–1967. Michele Sarà and Giovanni Salamanna make a series of explorations of the Tremiti Islands in the context of a research on island populations promoted and financed by the National Research Council, in this specific case entrusted to the Institute of Zoology and Comparative Anatomy of Bari University. Data regarding Scarabaeidae family are published by Salamanna (1968).

1968–1976. Helio Pierotti visits Pollino, Sila and Aspromonte on several occasions and announces the results regarding genus *Aphodius* in 1977. Between 1969 and 1973 even Giovanni Dellacasa

repeatedly goes to Sila and Aspromonte and the author's results are included in Pierotti's work (1977).

1968. In the month of July the author's personal searches in southern Italy begin, assiduously lasting for over 40 years for periods varying from 1 to over 20 days. The results of this research have been published only very partially in a series of twenty-eight works, some of which are dedicated to specific areas: Policoro (1986, with F. Montemurro), Pollino (1986), Gargano (1987), Sila (1991), Lago Pantano di Pignola (1996), light traps in Laghi Pantano di Pignola and San Giuliano (1998); other data were recorded in works dedicated to specific families: Hydradephaga (1972–1984), Hydrophilidae (1973 and 1974 with G. Ferro), Ptiliidae (1997, with M. Sörensson), Carabidae (1997, with V. Monzini), Curculionoidea (1997, with R. Caldara), Latridiidae (1999, with W. Rücker), Leiodinae (1985–1995), Cryptophagidae (1981, 1984 and 1996 with J.C. Otero), Malachinii (2001, with C. Pasqual), Phalacridae (1995, with Z. Švec) and Pselaphinae (2001, with G. Sabella). More than 500,000 specimens were collected overall, all studied by specialists (except for several Staphylinidae, Ptiliidae, Nitidulidae, Scydmaeninae, Mordellidae, Scraptidae, Bruchinae, Phalacridae, Corylophidae, Alexidae) and belonging to over 4,500 species. Data also appear in publications of many other authors, including descriptions of about one hundred new species.

1973. As part of the Verona Museum's Programs, Roberto Pace undertakes a series of research in Central southern Apennines and visits in particular Gargano, Pollino Massif, Orsomarso Mountains, Serre Calabre, Sambiase and Aspromonte. He describes many hypogeous new species in a total of thirteen publications (1974b–2002).

It is deemed of no use to report the researches undertaken after the 1970s, when connections became easier and many were the entomologists who visited the southern regions. Related data are dispersed in an endless series of works (well over 300, with descriptions of more than 140 endemic species) while there are no coordinated research campaigns with overall publication of the data.

From the late 1980s to date, Pietro Brandmayr and his collaborators have been a reference point for entomological research mainly in Sila, but also

in other territories from Aspromonte to Pollino. Their research, though essentially aimed at ecological studies, in particular about Carabidae used as environmental indicators, has not left out the other Coleoptera families, especially the saproxylic beetles. With their results they have produced dozens of works, both of divulgative and scientific nature, also including descriptions of new species.

MATERIAL AND METHODS

Study areas

Only in the last thirty years the eight areas covered by this study have been gradually placed under special protection through the establishment of several National and Regional Parks. Entomological research, on the other hand, as described above, has a much longer history and the writer himself has done most of his research before such protected areas were created.

It is not always easy to give an interpretation of the borders that entomologists, especially in the past, have attributed to these areas. Their specimens were often labeled only with generic toponyms such as "Gargano", "Sila", "Aspromonte", etc., and usually the meaning was in a geographical sense, the one marked by natural boundaries. We must nevertheless bear in mind that in some circumstances these natural elements (like woods, lakes, marshes, lagoons, etc.) may have undergone drastic changes, both in extension and in quality, due to the anthropic impact in the last few centuries, a phenomenon much accelerated in the most recent decades. This caused the "contraction" of several natural boundaries compared to how they were in the past.

Another factor to be considered, on the opposite side, is that the newly defined Parks perimeters in some cases excluded shorelines, wet areas, or portions of forests of considerable interest, environments which were often included in the areas of activity of entomological expeditions.

From this it follows that only in specific circumstances the delimitation of the areas under study coincides quite faithfully with the administrative borders of the respective newly established protected areas (such as in Policoro Wood, Mount Vulturne-Monticchio Lakes, Pantano Lake of Pignola)

while this does not happen in other areas such as Gargano Promontory, Pollino Massif, Sila Plateau and Aspromonte. For this reason, it is here considered appropriate to briefly explain the boundaries as they were historically meant and which ones are adopted in this work, they are those generally meant in the "entomological" sense.

The study areas located in Apulia, Basilicata and Calabria are respectively indicated in figures 2, 3 and 4.

1. Gargano promontory (Apulia: Foggia province, Fig. 2) is a karst plateau that stretches out towards the Adriatic Sea, almost devoid of a superficial river network. It includes a great variety of peculiar environments ranging from the millenary Foresta Umbra to the Mediterranean scrub, from coastal lagoons to pre-desert hills and plains.

All records to the east of an ideal line linking the mouth of Fortore river with Poggio Imperiale, Apricena, San Marco in Lamis, San Giovanni Rotondo and Manfredonia have been included. The Gargano National Park (established by Law No. 394 of 6.12.1991) is part of this territory, but excludes the south-eastern coast between Vieste and Torre del Segnale, wide areas between Lake Varano and Capriano-Vico del Gargano as well as all the territories south of Lesina Lake.

Gargano Promontory was explored, from an entomological point of view, since 1887 but initially just a few finds were disclosed. Almost 20 years

later, in 1906–1907, Holdhaus and his collaborators carried out long and thorough researches and the overall results were announced by Holdhaus himself (1911). In the following years the territory has been the subject of several researches promoted both by individual entomologists and by public institutions and many general works or dedicated to single families have been published.

The writer undertook research in this area in the years 1970–1984 and published the overall results in a general catalogue in 1987; after this date he carried out further significant research aimed mainly at the investigation of the soil fauna.

2. Policoro Wood (Basilicata: Matera province, Fig. 3). The Riserva regionale Naturale Orientata Bosco Pantano di Policoro was established with L.R. n. 28 of 08.09.1999.

On the Ionian coast, historically, there was one of the southern most important floodplain forests, partially marshy, comprising the nuclei of Pantano soprano and Pantano sottano. In the XVIII century the extent of the forest was already much reduced but it was still described by travellers as an enchanted, luxuriant and uncontaminated place devoid even of viable trails. Nowadays only a very small portion of the old and renowned wood remains, with a limited naturalness degree, along the course of the river Sinni downstream of the Metaponto-Sibari railway and to the southeast of the interpoderal road that runs parallel to the railway at about 300 meters. An area of reforestation, mainly of *Pinus halepensis*, *Eucalyptus camaldulensis* and *E. globulus*, has been included in the Reserve, east of the municipal road that leads from Policoro Wood to the dewatering system. The occasional floods of Sinni river pour debris on its outfall that sometimes carry an exceptional quantity of invertebrates (for example, on 17.IX.2000 sifting the beached debris, over 300 Coleoptera species were found).

The first entomological researches carried out on Policoro Wood are quite recent as they date back to 1956–1958 and the results were announced in a series of works that appeared between 1959 and 1979; the site gained notoriety and in the following years was the object of many explorations by entomologists from all over Italy but only a small number of the results was published in an organized manner, while many data were scattered in several papers.

Figure 2. Apulia (Italy): 1. Gargano Promontory.

The writer, together with his friend Fernando Montemurro, has done research here in the years 1976–1984 and published the overall results in a general catalogue in 1986. After this publication he carried out further research whose data are reported with the abbreviation “N” in the respective column of Table 1.

Parks of Lucanian Apennines (sites 3, 4, 5 and 6). The Lucan Apennines is a section of the southern Apennines that stretches as an arc from the Sella di Conza (between Campania and Basilicata) to Passo dello Scalone (in Calabria). It is bordered by the Ofanto river to the north, Sele to the west, Bradano to the east, from the Tyrrhenian to the south-west, from the plain of Sibari and the Gulf of Taranto to the south-east and also includes the mountains of Cilento in Campania and Orsomarso in Calabria.

The author gathered data all across this wide sector of the Apennines. For some areas he got a significant number of records on the coleopterological fauna (over a thousand species) and each of these areas will be separately treated: 3) Parks of Mount Vulture-Monticchio Lakes, 4) Regional Reserve of Pantano Lake of Pignola, 5) the complex Central Lucan Apennines-Sellata-Volturino-Viggiano-The Lagonegrese and Sirino massif, 6) Pollino National Park (partially). Below is a brief description of these sites, whose location is shown in figure 3, and respective National and Regional Parks exact designations based on the establishment acts.

On other areas of the Lucan Apennines, namely Cilento and Orsomarso Mountains, particularly interesting data are known as well as records referred to new species, but unfortunately not numerically significant, which is why it was preferred to omit them in this study.

3. Mount Vulture-Monticchio Lakes (Basilicata: Potenza province, Fig. 3) includes both the Parco Naturale Regionale del Vulture (established with L.R. n. 28 of 20.11.2017) and the Riserva Regionale Lago Piccolo di Monticchio (established with D.P.G.R. n. 1183 of 30.08.1984).

The woods of Mount Vulture, an ancient inactive volcano, surround two lakes of volcanic origin and are characterized by the remarkable variety of habitats and by very special microclimatic conditions which allow the presence of a low altitude beech forest (650 m a.s.l.). The site still has a suffi-

cient degree of naturalness despite the massive tourist exploitation.

The first entomological researches on Mount Vulture and its lakes date back to 1880 and were made known two years later in a list including species collected also in other sites. In XX century the place was visited by numerous researchers with data published in several works. The entomological findings deduced from these contributions come from a small area around Mount Vulture: the summit, the territories adjacent the two lakes of Monticchio and the road that links the town of Rionero in Vulture to Mount Vulture.

The writer began occasional explorations in this area in 1970. A particularly intense period of research followed in the years 2000–2003, after which he drafted a report and a detailed list of collected species that he delivered to Basilicata Region.

4. Pantano Lake of Pignola (Basilicata, Potenza province, Fig. 3) was established as Riserva Regionale Lago Pantano di Pignola with D.P.G.R. n. 795 of 19.06.1984.

The lake, which occupies a piedmont depression at 750 m a.s.l. bounded to the north by Serra Stantiere, to the west by the ridges of Petrucco relief and to the south by the watershed of La Rocca, is managed by WWF and has a fair degree of naturality, although before being fenced it was subject to considerable upheavals. The reduced slope of the banks allows diversified aquatic vegetation, while the meadows and the sparse arboreal vegetation in contact with this ancient wetland are rich in ecological niches that make it an area of high biodiversity.

The only entomological researches on Pantano Lake of Pignola were conducted by the writer in the years 1991–1994 and were carried out along the entire perimeter of the lake, already fenced at the time. The results were released in a special publication by the WWF in 1996. After this publication further research was undertaken, the data of which are shown with the symbol “B” or “N” in the respective column.

5. Central Lucan Apennines-Central area Province of Potenza (Basilicata: Potenza and Matera provinces, Fig. 3) here refers to the “Sellata-Monte Croccia-Monte Volturino-Viggiano-Lagonegrese-Sirino massif” complex.

It is a complicated mountain system that constitutes the central backbone of Lucan Apennines, which varies in landscape from the harsh and almost dolomitic aspect of the northern peaks to the more gentle mountains of the Maddalena, to return to the grandeur of Mount Sirino massif and Mount Alpi in the southernmost offshoots. The whole territory is rich in woods that in the lower altitudinal zone are constituted by evergreen oaks and thermophilous broad-leaved trees and in the upper zone by *Quercus cerris* and mixed beech-woods, as well as some isolated chestnut groves and the residual forest of Abetina di Laurenzana, which hosts a local variety of *Abies alba*.

The entomological data shown come from places located between the middle and upper course of Basento and Sinni rivers; the north-western border lies between the sources of the Basento river (Fossa Cupa) and the villages of Brienza and Atena Lucana; the south-western boundary runs along the border with Campania region up to Lagonegro and, near Lauria, joins the Sinni river which represents its southern border thus including Mount Sirino and Mount Alpi; the southeast boundary is an ideal line connecting Salandra with Stigliano, Sant'Angelo and Valsinni.

In this area we find the following Reserves and National Parks:

- a. Riserva Nazionale Naturale Antropologica Monte Croccia (established with D.M.A.F. of 11.09.1971);
- b. Parco Regionale Gallipoli Cognato e Piccole Dolomiti Lucane (established with L.R. n. 47 of 24.11.1997);
- c. Riserva Regionale Abetina di Laurenzana (established with D.P.G.R. n. 2 of 4.01.1988);
- d. Riserva Regionale Lago Laudemio (established with L.R. n. 42 of 22.05.1980 and D.P.G.R. n. 426 of 19.04.1985);
- e. Parco Nazionale dell'Appennino Lucano Val d'Agri Lagonegrese (established with D.P.R. of 8.12.2007);
- f. A small part of Pollino National Park that protrude to the north of Sinni river and which, of significance, includes Mount Alpi.

News of the first research in Central Lucan Apennines dates back only to 1909 and there is no work of synthesis on the Coleoptera fauna; rather, there are many data dispersed in a myriad of works

even with description of new species which refer to the second half of the last century.

The writer has carried out several researches, generally of short duration (1–5 days), between 1980 and 2000, but so far he had communicated only single data in contributions dedicated to specific families despite having found over 1,000 Coleoptera species.

6. Pollino Massif (Basilicata: Potenza and Matera provinces, Calabria: Cosenza province, Fig. 3). Parco Nazionale del Pollino was established with Law n. 67 of 11.03.1988; with subsequent acts and decrees the perimeter has been extended (Law n. 305 of 28.8.1989, D.M. of 31.12.1990, D.P.R. of 15.11.1993 and D.P.R. of 2.12.1997) so that it currently represents the largest national park in Italy. In it we find Riserva Naturale Biogenetica Statale Rubbio and Riserva Naturale Orientata Gole del Raganello in Basilicata, Riserva Naturale Statale Valle del Fiume Lao and Riserva Naturale Orientata Valle del Fiume Argentino in Calabria (Orsomarso mountains).

The Pollino Massif includes all the highest peaks of southern Apennines, whose forms have been shaped by the ancient glaciations and which for part of the year are covered by snowfields. The alternation of karstic phenomena and morainic deposits makes the landscape very evocative. Some

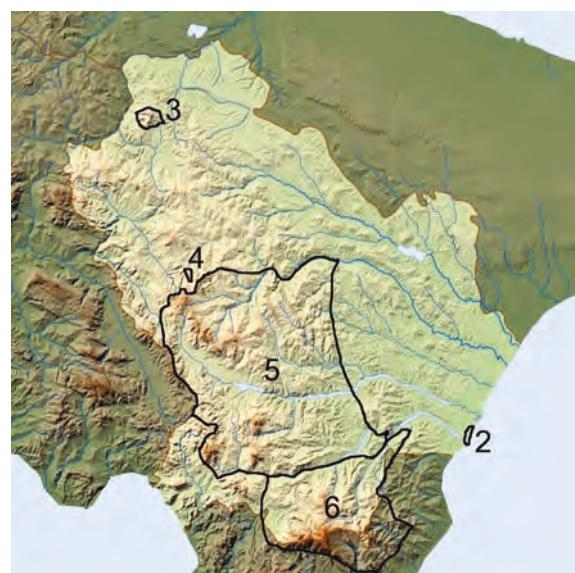

Figure 3. Basilicata (Italy): 2. Policoro Wood; 3. Mount Vulture-Monticchio Lakes; 4. Pantano Lake of Pignola; 5. Central Lucan Apennines; 6. Pollino Massif.

plant associations are unique to this area, where for example at the highest altitudes rare relict populations of *Pinus leucodermis* can be found. Also chestnut groves, oak woods and beech woods show noteworthy characteristics.

Considering the origin of most of the data, here it was intended for "Pollino" the whole area that includes the peaks of Monte Pollino, Serra del Prete, Dolcedorme, Serre di Crispo and Ciavole, Coppola di Paola and the neighboring territories; very different is the current perimeter of Pollino National Park extending from the Tyrrhenian to the Ionian.

Boundaries of Pollino Massif pass therefore to the north along the course of Sinni river from Episcopia (Potenza province) to Valsinni (Matera province), to the east and west follow the border with Calabria region but protrude widely from it at Alessandria del Carretto up to Francavilla Marittima where the southern border follows the course of Raganello stream and from here the localities of Frascineto, Morano Calabro, Campotenese and Mormanno. Pollino Massif shows a barely acceptable state of naturalness, although the anthropic impact is definitely excessive and favored both by the construction of new roads and by poor surveillance.

The first research on Pollino Massif dates back to 1880 and was published in 1882. Later it was the subject of studies whose results were only partially published; starting from the middle of last century wider research campaign were promoted by Naples University and finally the results were published in 17 works dedicated to Coleoptera. Several other researches have been carried out by single entomologist whose data were dispersed in many papers or made known in contributions dedicated to single families.

The writer used to explore Pollino Massif in the years 1969-1985 and he published the overall results in a general catalogue in 1986. Later he further investigated the area until around 2000, collecting nearly 500 further species.

7. Sila Plateau (Calabria: Cosenza, Catanzaro and Crotone provinces, Fig. 4). Parco Nazionale della Sila was established with Law n. 344 of 8.10.1997 and D.P.R. of 14.11.2002. In 2014 the site was included in the UNESCO Man and Biosphere Program.

It is one of the areas that are historically less populated and with the highest percentage of wooded surface of Italy. The plateau is made up of igneous

and metamorphic rocks that clearly differentiate it from the calcareous bulk of the Apennines and that influence the form of the landscape, as well as that of the vegetation. In fact, at high altitudes, *Pinus nigra laricio* dominates and, even higher, *Fagus sylvatica*, frequently interspersed with *Abies alba*.

The data considered in this work and often reported by the authors as "Sila" concern an area that extends far beyond the boundaries of Sila National Park, as it includes wide wooded areas to the north and east of Cecita Lake and both east and west of Ampollino Lake as well as to south of the latter. As far as man's impact is concerned, the same is true as for what was said about Pollino Massif, though the situation is slightly better.

The first researches in Sila Plateau date back to 1859, but these results were never disclosed. Later it was the subject of further explorations, of which only some were published in their entirety in 1881, 1941 and 1943, while other data were dispersed in a myriad of contributions. In the 1960s the territory was the subject of a research project promoted by Verona Museum and the results relating to some of the families were announced in several papers. Meanwhile and subsequently the Pollino Massif had become the destination of a large number of entomologists whose results were only partially communicated in numerous contributions.

The writer in the years 1969-1988 visited Sila Plateau several times for periods of 7-15 days and therefore disclosed the results of its collections in a general catalogue in 1991.

8. Aspromonte (Calabria: Reggio Calabria province, Fig. 4). Parco Nazionale dell'Aspromonte was established with Law n. 305 of 28.08.1989, D.P.R. of 14.01.1994 and D.P.R. of 19.07.2008).

This is a mountainous massif with a jagged topography occupying the southernmost tip of the Stivale (the Boot: in a figurative sense, par excellence, Italy, so called because of its geographical shape that resembles that of a boot) and whose flora and fauna are extremely heterogeneous due to multiple factors: the low latitude, the elevation height differences, the presence of tectonic terraces as well as the proximity of the sea and the different exposure of mountainsides respect to this. Like Sila Plateau, Aspromonte consists of rocks more similar to Alpine ones than those of the Apennines, and also here in the woods the *Pinus nigra laricio* is predominant above 800 m,

while from the 1,200 m and at higher altitudes the prevailing tree cover is *Fagus sylvatica* and *Abies alba*. A peculiar feature of superficial hydrography is the "fiumara", a characteristic type of watercourse with a very wide pebbly bed and for most of the year dry, but seasonally subject to flash floods.

In this work, Aspromonte is meant in a geographical sense and therefore is that area located south of Petrace river and of "fiumare" of Platì and Càreri; it is thus considered a portion of territory that is more than double in area compared to that of the National Park. This choice was made both to include the many data reported over almost two centuries of entomological investigations and to not exclude the fauna of the coasts, which has particularly interesting but different species to that of the mountainous areas.

It should be noted here that mainly the fauna of south-eastern territories, riparian and not, between Locri and Ionian Saline is particularly interesting also because of the different geology, nature of the soil, and the degree of man's influence compared to that of the territory located to the west between Rosarno and Reggio Calabria. The general impact of man's activities is more or less analogous to that of other National Parks of southern Italy, consider-

ing that "Park" in this region often means uncontrolled tourism and illegal building rather than carefully safeguarding the natural environments that remain.

Of the eight sites here treated, Aspromonte, approached by sea from Sicily, is the one that was first investigated with research dating back to 1783, the results being announced three years later. Further studies bear dates of the first half of XIX century demonstrating the attraction that this site had already gained among entomologists two centuries ago. The research continued discontinuously and with data published only partially until the mid-twentieth century, when Aspromonte was the object of accurate research by members of the expeditions promoted by Verona Museum and the results concerning some families were announced in various papers. In the following years further short journeys were made by several entomologists, some of whom did not publish any results and others who did so sporadically in various works.

The writer visited Piani d'Aspromonte for the first time around 1975 and until 2000 undertook many and accurate researches, though the results until now were released only minimally in various publications dedicated to single families.

Samples

In order to integrate and update the previous catalogues, all the publications that could be found were consulted. Every paper bearing data on southern Italy has been carefully examined, and possible synonymies and taxonomic status changes have been checked.

Furthermore, the new records resulting from the research carried out by the author himself after the publication of the aforementioned catalogues are reported.

For field research, a wide range of collecting techniques has been used, mainly on sight, with collecting nets, entomological umbrella, sifting (of leaf litter, rotten wood, hay, mushrooms, dung, soil under stones in meadows or woods, etc.) combined with the use of Winkler/Moczarski extractors, light traps, collecting net for aquatic beetles, aerial and pitfall traps both with and without attractive baits.

All the study material has been identified by specialists but substantial quantities of specimens are still undetermined (17,000 Staphylinidae,

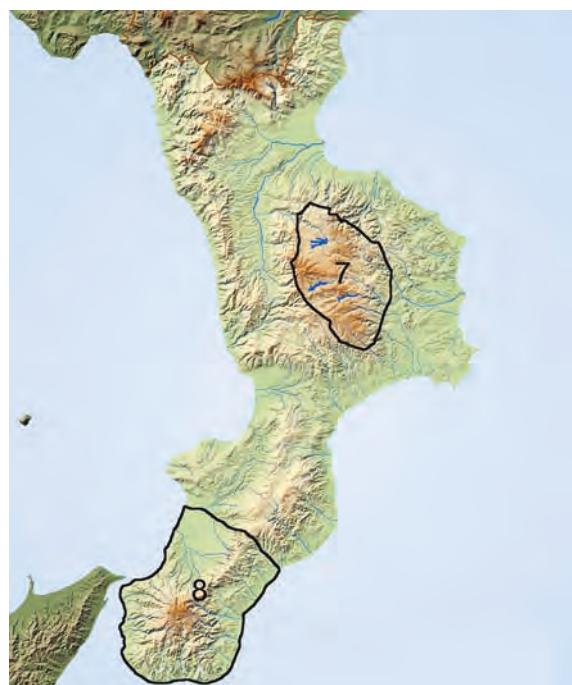

Figure 4. Calabria (Italy): 7. Sila Plateau; 8. Aspromonte.

10,000 Ptiliidae, 7,500 Nitidulidae, 3,700 Scydmaeninae, over 3,000 Mordellidae and Scraptiidae, 2,100 Bruchinae, 1,700 Phalacridae, 1,700 Corylophidae, 1,300 Alexiidae, 600 Clambidae).

Most of the specimens collected by the writer are kept in the author's personal collection, currently deposited at the Museum of Natural History, Section of Zoology, of Florence University.

The results are shown in Table 1, in which the families are listed according to the taxonomic order adopted by Bouchard et al. (2011).

For the nomenclature, the status and the sequence of subfamilies and tribes within of families, reference was made to volumes 1–8 of the "Catalogue of Palaearctic Coleoptera", with some adjustments according to the works listed below:

- Ptiliidae: Sörensson & Delgado, 2019
- Elateroidea: Kundrata et al., 2014
- Elateridae: Kundrata et al., 2018
- Drilini: Kundrata & Bocak, 2011
- Cebrionini: Kundrata & Bocak, 2011
- Peltidae: Gimmel et al., 2019
- Lophocateridae: Gimmel et al., 2019
- Trogossitidae: Gimmel et al., 2019
- Thymalidae: Gimmel et al., 2019
- Rhadalidae: Bocakova et al., 2011; Gimmel et al., 2019
- Malachiinae: Gimmel et al., 2019
- Dasytinae: Gimmel et al., 2019
- Cucujoidea - Coccinelloidea: Robertson et al., 2015
- Nitidulidae: Cline et al., 2014
- Cybocephalidae: Cline et al., 2014
- Teredidae: Robertson et al., 2015
- Anamorphidae: Robertson et al., 2015
- Mycetaeidae: Robertson et al., 2015
- Curculionoidea: Alonso-Zarazaga et al., 2017

Also consulted were the works of Źyła & Sologubnikov (2019), Vasilikopoulos et al. (2019) and Zhang et al. (2018) but it was considered more appropriate not to take them into account here.

Names, initials and diacritical marks of the various authors have been verified on Bousquet (2016).

Species, contrariwise, are listed in alphabetical order for the simple fact that names of eventual subgenus have been omitted to make the "Species" column more manageable.

The species lists, subdivided by family, were subjected to a critical examination by the colleagues referred to in the "Acknowledgments" chapter, who

reviewed the taxonomic status and added unpublished data eventually in their possession.

Taxonomic status of species and of superior categories is updated to 31.12.2019.

Symbols used in Table 1:

X: species previously reported in the author's catalogues of Gargano Promontory, Policoro Wood, Pantano Lake of Pignola, Pollino Massif and Sila Plateau;

B: new bibliographic data, relating to the areas already mentioned as well as to Mount Vulture-Monticchio Lakes, Central Lucan Apennines and Aspromonte. In cases where the presence of a species in a given area is documented both in the bibliography and in CKmap, it was preferred to report the record with the symbol "B";

CK: data resulting from "CKmap" (national database) if not otherwise published;

H: Holdhaus citations (1911) concerning Gargano Promontory and omitted in the author's previous contribution to this promontory (Angelini, 1987);

N: new data from the author, if not already mentioned in other publications and then reported with the symbol "B";

!: records added by specialists who have reviewed the families of their competence: Paolo Audisio (Hydraenidae and Nitidulidae), Cesare Bellò (Curculionidae), Mauro Daccordi (Chrysomelidae), Jiří Háva (Dermestidae), Francesco Izzillo (Buprestidae and Cerambycidae), Leonardo Latella (Carabidae), Carlo Leonardi (Apticinae), Gianfranco Liberti (Rhadalidae and Melyridae), Andrea Liberto (Oedemeridae), Gianluca Magnani (Buprestidae), Alessandro Mascagni (Elmidae and Dryopidae), Antonio Mazzei (Carabidae), Giuseppe Platia (Elateridae), Roberto Poggi (Pselaphinae), Saverio Rocchi (Helophoridae), Davide Sassi (Chrysomelidae), Pierpaolo Vienna (Histeridae), Adriano Zanetti (Staphylinidae), Iuri Zappi (Cleridae).

[E]: endemic species.

The "IUCN Category" column shows the IUCN (International Union for the Conservation of Nature and Natural Resources) Categories, as adopted in the Italian Red Lists of saproxylic Coleoptera referred to, compiled by Audisio et al. (2014) and Carpaneto et al. (2015), and the same abbreviations are used.

Table 1. THE LIST OF SPECIES found in the eight study sites.

CONCLUSIONS

The latest author's research as well as the data available in literature have greatly increased the number of known species in the surveyed areas. The situation that emerges is summarized in following Table 2.

The presence of saproxylic species in the study sites is rather conspicuous; in fact, they amount to 56.1% of the overall saproxylic species known for Italy. However, this figure should not be misleading, since the last column of following Table 3 shows that the "Critically endangered" (CR) species make up just 25.9% of the total on Italy and the "Endangered" species (EN) and "Vulnerable" (VU) account for 27% and 40% respectively.

It can be deduced that the level of research, especially in some of the areas, is not yet sufficiently exhaustive and that the sites subject of the survey suffer from a considerable degree of anthropization or incorrect management of wooded areas, so that the entomofauna of special conservation interest proves to be, to some extent, impoverished. In many recent papers on saproxylic fauna the need to maintain a certain amount of dead wood in the forests is underlined, a good practice that unfortunately is often not applied.

According to the fifty-year experience of the author researching Coleoptera, it would be necessary to establish integral nature reserves in ancient woodland as well as regulating livestock grazing in grasslands that are increasingly depleted.

It is considered useful and necessary, mainly in the perspective of future research, to comment on the data presented here despite the fact that it is difficult to separate the mere judgment based on sterile numbers from personal sentiment, because these are places that the author investigated for more than four decades (starting from distant 1968) witnessing too many changes, often irreversible, with consequent progressive decline of the fauna.

Particularly, from an examination of the data summarized in Tables 2 and 4, it clearly emerges that only the Coleoptera fauna of Policoro Wood can be considered sufficiently studied. With its 2,353 species collected in an area of just 680 hectares, this site is perhaps one of those that show greater biodiversity throughout the Mediterranean basin. The reasons are many: it is an ancient floodplain forest with a quite varied and dense vegetation so that it preserves a certain microclimate and, although today reduced to a very small portion of those forests that once covered the entire Metapontino, for this same reason it represents a last exiguous shelter for all those forest dwelling species that have undergone the inexorable erosion of their habitat; it is also placed in a favorable position at the mouth of Sinni river which, especially before the construction of the Monte Cotugno dam, during the floods washed downstream huge quantities of debris, and with them species, from inland; last but not least, studies here have been conducted extensively by researchers of several disciplines.

Table 3. Number of saproxylic species in each of the surveyed areas, compared to the total and percentage for Italy (CR: Critically Endangered; EN: Endangered; VU: Vulnerable; NT: Nearly Threatened; LC: Least Concern; DD: Data Deficient; NA: Not Applicable).

Even the Coleoptera fauna of Pantano Lake of Pignola can be considered sufficiently known taking into account the features and limited extent of this site, as evidenced by the high number of species typical of meadow areas and of lakes shores that it shows.

In the district of Mount Vulture-Monticchio

Lakes, despite the relatively small size, the number of species surveyed is probably less than the expected total considering the peculiar characteristics of the biotope.

Gargano Promontory, although explored at length by several researchers and given the variety of environments and the extension, records a num-

ber of species (2,591) decidedly lower than a realistic estimation. It can be assumed that especially the fauna of the coasts, where saved by the tourist encroachment and pressure, should still reveal many novelties.

Fauna of Central Lucan Apennines, known for over 2/3 on the basis of published or unpublished personal data, could prove to be more abundant, as shown by particularly targeted research conducted by other entomologists in the Gallipoli-Cognato woods.

Faunal total of Pollino Massif, in the light of the many and often interdisciplinary researches it has been subjected to and the fact that most of the data comes from territories located over 1,000 meters above sea level, can be considered sufficiently investigated and close to the real one.

As far as Sila Plateau is concerned, the data possessed or deduced from bibliography are decidedly incomplete; it is to be regarded as the site whose fauna is less well known, especially that of the soil, as will be discussed later about Staphylinidae.

The Aspromonte, curiously, shows a species number almost similar to that of Gargano Promontory with which it shares, broadly, also the territorial extension, despite having been less investigated. And like Gargano Promontory, it is believed that the currently known fauna of Aspromonte, based for 1/3 on mostly previously unpublished personal data, is partially incomplete and that more data may emerge from research aimed at the study mainly of floricolous species both of mountainous areas and of the shorelines least damaged by human impact.

A numerical analysis of the presence of the various families in each of the sites (Table 4) confirms and amplifies what has been remarked above. Taking into account the 12 families represented by over 100 species in this study, the following observations can be made:

- Ptinidae (103 species): in Pollino Massif, Policoro Wood, Aspromonte and Gargano Promontory the number of species varies between 47–54 (equal to approximately 50% of the treated species); the 27 and 34 species recorded for Mount Vulture-Monticchio Lakes and Central Lucan Apennines are believed not to fully represent the actual presence of this family in these areas, while the low number of species known for Pantano Lake of Pignola is to be attributed to the particular features of the site.

- Nitidulidae (113 species): represented on average by 51–68 species, the high and significant number of species known for Pollino Massif (87, that is 77% of total) stands out, while the 30 species known for Mount Vulture-Monticchio Lakes are to be considered heavily underestimated; regarding this family it should however be noted that 7,500 specimens collected by the author are still undetermined.

- Elateridae (117 species): represented on average with about 53–63 species, the positive peak of 77 species for Pollino Massif should be noted while the lesser total of 22 for the Pantano Lake of Pignola is largely imputable to the particular characteristics of the site; Sila Plateau and Aspromonte confirm that they have a similar trend (75 and 72 species respectively).

- Brentidae (*sensu lato*) (134 species): it is interesting to note how Gargano Promontory, Pollino Massif and Aspromonte are settled on 76–80 species while Policoro Wood has a strange smaller peak of 47 species, similar to that of Central Lucan Apennines. The number of species known for Pantano Lake of Pignola is significant, 52 species, reflecting the high biodiversity of this site regarding the floricolous fauna, a situation also found for other families not discussed here (Coccinellidae).

- Buprestidae (135 species): in this family a high number of known species is recorded for Pollino Massif (96, equal to 71.1% of the total) and Policoro Wood (95); the other sites have 70–77 species while the small number of Pantano Lake of Pignola stands out, 21 species collected only in meadows surrounding the lake, given the almost total absence of trees nearby.

- Tenebrionidae (147 species): family whose species have a remarkably diversified ecology, not by chance for Aspromonte, Gargano Promontory and Policoro Wood, therefore sites that include shorelines, 77–90 species are known (90 for the first site) while Central Lucan Apennines, Pollino Massif and Sila Plateau stand on 48–61 species; the lesser total of just 20 species of Pantano Lake of Pignola is due to its peculiar geomorphological characteristics.

- Scarabaeidae (169 species): the average number in most sites (five) varies between 87 and 99 species; the primacy of known species belongs to Aspromonte (120) and the negative one to Pantano Lake of Pignola (just 29).

Table 4/3. Number of species, per family, in each of the sites, in the Italian Red List of saproxylic Coleoptera and total.

- Cerambycidae (181 species): the numerical dynamics of this family that accounts for the greatest quantity of saproxylic species is particularly important and significant; while Pollino Massif shows up for the greater number of species (120), Pantano Lake of Pignola is confirmed as having the least diverse fauna with just 25 species; indicative is the clear difference, generally not perceptible, between the fauna of Gargano Promontory and that of Aspromonte, 107 and 89 species respectively, while strangely Policoro Wood with 84 species places itself below Sila Plateau and Central Lucan Apennines which count, respectively, 101 and 105.

- Chrysomelidae (427 species): Gargano Promontory with 237 species has the highest expression of biodiversity, while the discrepancy between Pollino Massif (223 species) and Aspromonte (205) validates what has already been said regarding the further research needed on the latter. Sila Plateau as well, with just 176 species (181 for Policoro Wood), confirms how little this area has been investigated. Mount Vulture-Monticchio Lakes with 107 species require further in-depth research, while Pantano Lake of Pignola with 161 species corroborate a high biodiversity for the species linked to the meadows.

- Carabidae (475 species): Aspromonte (278 species) is the significantly richest area, while four

sites follow with a number of species ranging between 201 (Sila) and 233 (Gargano); Policoro Wood, despite its small size, with 253 known species far exceeds the remaining sites.

- Curculionidae (750 species): it is perhaps the only case in which Gargano Promontory shows the greatest richness with 382 species and reaffirms the contrast already noted with Aspromonte which counts only 320; Sila Plateau and Central Lucan Apennines stand respectively on 259 and 258 species, while Pantano Lake of Pignola and Mount Vulture-Monticchio Lakes have only 157 and 159 species; the Pollino Massif with 350 species sees its high biodiversity confirmed.

- Staphylinidae (853 species): particularly interesting and enlightening for future research and to understand the current state of the same is the analysis of the presence of this important family, mainly linked to the soil: Aspromonte stands out with 431 species that is 201 more than the nearby Sila Plateau (which would be the last, if not for the much smaller sites of Pantano Lake of Pignola and Mount Vulture-Monticchio Lakes); Gargano Promontory, Central Lucan Apennines and Pollino Massif vary between 368 and 400 species, while Policoro Wood, despite its small surface area, numbers 319 species; it should however be emphasized that the writer's contribution to the knowledge of this family was

much lower than for other families, as 17,000 collected specimens are still unidentified.

On the basis of what has just been explained, it can be concluded that the research on the floricolous and saproxyllic beetles of Aspromonte should be further increased, and that the fauna of the soil is still to be investigated more widely and in more detail, mainly in the Sila Plateau and Gargano Promontory. Policoro Wood and the Pollino Massif show a state of knowledge that can be considered acceptable, while Mount Vulture-Monticchio Lakes are further to be studied at a general level.

ACKNOWLEDGEMENTS

I would like to thank my colleagues and friends who, with effective collaboration and generosity, have spent time reviewing the families of their competence, sending papers and sharing valuable data, thus making it possible to accomplish this study and bring it up to date: Paolo Audisio (Università la Sapienza, Dipartimento di Biologia e Biotecnologie "Charles Darwin", Roma, Italy), Xavier Bellés (Institute of Evolutionary Biology (CSIC-UPF), Barcelona, Spain), Cesare Bellò (Castelfranco Veneto, Italy), Alessandro B. Biscaccianti (Laboratorio di Entomologia ed Ecologia Applicata (LEEA), Dipartimento PAU, Università Mediterranea di Reggio Calabria, Italy), Lech Borowiec (Department of Biodiversity and Evolutionary Taxonomy, University of Wrocław, Poland), Milan Boukal (Pardubice, Czech Republic), Roberto Caldara (Milano, Italy), Benjamin Calmont (Société d'Histoire Naturelle Alcide-d'Orbigny, Aubière, France), Enzo Colonnelli (Roma, Italy), Gianfranco Curletti (Museo Civico di Storia Naturale, Carmagnola, Italy), Mauro Daccordi (Verona, Italy), Luciano Diotti (Cinisello Balsamo, Italy), Michael Eifler (Pinneberg, Germany), Roberto Fabbri (Museo Civico, Sezione Naturalistica, Bagnacavallo, Italy), Gabriele Franzini (Milano, Italy), Carlo Giusto (Recco, Italy), Jiří Hájek (Department of Entomology, National Museum, Praha, Czech Republic), Jiří Háva (Private Entomological Laboratory and Collection, Prague-west, Czech Republic), Francesco Izzillo (Napoli, Italy), Jiří Kolibáč (Moravian Museum, Department of Entomology, Brno, Czech Republic), Ondřej Konvička (Institute

of Entomology, Biology Centre AS CR, České Budějovice, Czech Republic), Robin Kundrata (Department of Zoology, Faculty of Science, Palacky University, Olomouc, Czech Republic), Leonardo Latella (Museo Civico di Storia Naturale, Verona, Italy), Piero Leo (Cagliari, Italy), Carlo Leonardi (Museo Civico di Storia Naturale, Milano, Italy), Gianfranco Liberti (Ubaldo, Italy), Andrea Liberto (Roma, Italy), Gianluca Magnani (Cesena, Italy), Paolo Magrini (Firenze, Italy), Alessandro Mascagni (Firenze, Italy), Jan Matějíček (Hradec Králové, Czech republik), Antonio Mazzei (Università della Calabria, Museo di Storia Naturale della Calabria ed Orto Botanico, Rende, Italy), Josef Mertlik (Opatovice nad Labem, Czech Republic), Heinrich Meybohm (Großhansdorf, Germany), Vittorino Monzini (San Giuliano Milanese, Italy), Gianluca Nardi (Centro Nazionale Biodiversità Carabinieri "Bosco Fontana", Marmirolo, Italy), José Carlos Otero (Departamento de Zoología y Antropología Física, Universidad de Santiago de Compostela, Spain), Roberto A. Pantaleoni (Dipartimento di Protezione delle Piante, sezione di Entomologia agraria, Università degli Studi, Sassari, Italy), Guido Pedroni (Parco Regionale del Corno alle Scale, Marzabotto, Italy), Emanuele Piattella (Università la Sapienza, Dipartimento di Biologia e Biotecnologie "Charles Darwin", Roma, Italy), Giuseppe Platia (Gatteo, Italy), Pavel Průdek (Brno, Czech Republic), Pierpaolo Rapuzzi (Prepotto, Italy), Roberto Rattu (Cagliari, Italy), Johannes Reibnitz (Tamm, Germany), Antonio Rey (Genova, Italy), Saverio Rocchi (Firenze, Italy), Vito Antonio Romano (Potenza, Italy), Wolfgang Rücker (Neuwied, Germany), Rafal Ruta (Department of Biodiversity and Evolutionary Taxonomy, University of Wrocław, Poland), Jan Růžička (Department of Ecology, Faculty of Environmental Sciences, Czech University of Life Sciences Prague, Praha, Czech Republic), Enrico Ruzzier (Mirano, Italy), Davide Sassi (Castelmarte, Italy), Mikael Sörensson (Department of Biology, Lund University, Ecology Building, Lund, Sweden), Zdeněk Švec (Praha, Czech Republic), Dmitry Telnov (Natural History Museum, London, United Kingdom), Wioletta Tomaszewska (Museum and Institute of Zoology, Polish Academy of Sciences, Warszawa, Poland), Jiří Ch. Vávra (Ostrava Museum, Ostrava, Czech Republic), Pierpaolo Vienna (Lido di Venezia, Italy), Vincenzo Vomero (Roma, Italy), Piotr

Węgrzynowicz (Institute of Forest Sciences, University of Łódź, Branch in Tomaszów, Tomaszów Mazowiecki, Poland), Rafael Yus Ramos (Vélez-Málaga, Málaga, Spain), Petr Zahradník (Forestry and Game Management Research Institute, Jíloviště, Czech Republic), Adriano Zanetti (Verona, Italy), Iuri Zappi (Casalecchio di Reno, Italy), Stefano Ziani (Imola, Italy).

My special gratitude for advice, support in bibliographical research and careful review of chapters during the manuscript realization goes to Luca Bartolozzi (Museo di Zoologia “La Specola” dell’Università di Firenze, Italy), Maura Bocci (Centro Nazionale Biodiversità Carabinieri “Bosco Fontana”, Marmirolo, Italy), Roberto Poggi (Museo Civico di Storia Naturale, Genova, Italy) and Ignazio Sparacio (Palermo, Italy). I’d like to thank my friend Jonathan Cooter (Oxford University, Museum of Natural History, United Kingdom) for linguistic revision of the text.
